SECOND ORDER CUMULANTS OF PRODUCTS

JAMES A. MINGO$^{(*)}$, ROLAND SPEICHER$^{(*)(\dagger)}$, AND EDWARD TAN$^{(\ddagger)}$

Abstract. We derive a formula which expresses a second order cumulant whose entries are products as a sum of cumulants where the entries are single factors. This extends to the second order case the formula of Krawczyk and Speicher. We apply our result to the problem of calculating the second order cumulants of a semi-circular and Haar unitary operator.

1. Introduction

In a recent series of papers we have developed the notion of second order freeness [7], [19], [21], [22], [23], [25]. This was motivated by the need for a framework for recent work on the global fluctuations of the eigenvalues of ensembles of random matrices; see e.g. Ambjørn, Jurkiewicz, and Makeenko [1],Anderson and Zeitouni [2], Bai and Silverstein [3], Brézin and Zee [6], Diaconis [9], Johansson [13], Khorunzhy, Khoruzhenko, and Pastur [15].

Free independence, or what we shall call first order freeness, was created by Voiculescu [29, 30] as an adaptation of the usual notion of independence to the non-commutative algebra of matrix valued (or more generally operator valued) random variables. The central object of Voiculescu's theory is called the R-transform. For a random variable a, $R(z)$ is a formal power series, which in most examples is an analytic function. The coefficients of $R(z)$ are called the free cumulants of a.

The salient feature of Voiculescu's theory is that given the moments of freely independent random variables, there is a universal rule for calculating the moments of sums and products of these random variables. Second order freeness achieves for the *fluctuation moments* what first order freeness does for ordinary moments. Moreover for many of

the standard ensembles of random matrices, independent matrices are asymptotically free of second order, so the theory is quite widely applicable.

Speicher [26] developed a combinatorial approach to free cumulants based on the non-crossing partitions of Kreweras [18]. This enabled the theory to be used in many cases where analytic expressions could not be found. In particular in [17], Krawczyk and Speicher found the free analogue of the formula of Leonov and Shiryaev [20] for calculating cumulants where the entries are products. In this paper we shall extend this result to the second order cumulants introduced in [7].

We begin by motivating the definition of second order cumulants. Let $(A_N)_{N\in\mathbb{N}}$ be a unitarily invariant ensemble of random matrices. By definition this means that the joint distribution of the entries of A_N is the same as the joint distribution of the entries of UA_NU^*, where U is a $N \times N$ unitary matrix. We shall say that the ensemble $(A_N)_{N\in\mathbb{N}}$ has a *second order limit distribution* (c.f. [22, 3.4]) if for all integers p and q the limit

$$\alpha_p := \lim_N \frac{1}{N} E(\mathrm{Tr}(A_N^p))$$

exists, and for $Y_{N,p} = \mathrm{Tr}(A_N^p - \alpha_p I_N)$, the limit

$$\alpha_{p,q} := \lim_N E(Y_{N,p}Y_{N,q})$$

exists, and for all $r > 2$ and $p_1, p_2, \dots, p_r$

$$\lim_N k_r(\mathrm{Tr}(A_N^{p_1}), \dots, \mathrm{Tr}(A_N^{p_r})) = 0$$

where k_r is the r^{th} classical cumulant, or semi-invariant (see e.g. [20]). Elements of the sequence $(\alpha_p)_p$ are the moments of the limiting distribution. We shall call the elements of the sequence $(\alpha_{p,q})_{p,q}$ the *fluctuation moments* of the limiting distribution.

These two sequences of moments may be then used to define a *second order* non-commutative probability space on $\mathcal{A} = \mathbb{C}[x]$, the polynomials in the variable x. By a second order non-commutative probability space we mean a triple $(\mathcal{A}, \phi, \phi_2)$ where $\mathcal{A}$ is a unital algebra over $\mathbb{C}$, $\phi : \mathcal{A} \to \mathbb{C}$ is a tracial linear functional with $\phi(1) = 1$, and $\phi_2 : \mathcal{A} \times \mathcal{A} \to \mathbb{C}$ is a symmetric bilinear function which is tracial in each variable and $\phi_2(1, a) = \phi_2(a, 1) = 0$ for all $a \in \mathcal{A}$. Thus in our example we let $\phi(x^p) = \alpha_p$ and $\phi_2(x^p, x^q) = \alpha_{p,q}$.

In [7] we introduced the second order R-transform, which is a formal power series in two variables: $R(z, w) = \sum_{p,q\geq 1} \kappa_{p,q} z^{p-1} w^{q-1}$. The coefficients $(\kappa_{p,q})_{p,q}$ are called the second order cumulants of the second order distribution and they depend on the first and second order moments $(\alpha_p)_p$ and $(\alpha_{p,q})_{p,q}$ according to the functional equation given in [7, p. 11].

$$G(z,w) = G'(z)G'(w)R(G(z),G(w)) + \frac{\partial^2}{\partial z \partial w} \log\Big(\frac{G(z)-G(w)}{z-w}\Big) \tag{1}$$

where

$$G(z) = \frac{1}{z}\sum_{p\geq 0} \alpha_p z^{-p} \text{ and } G(z,w) = \frac{1}{zw}\sum_{p,q\geq 1} \alpha_{p,q} z^{-p} w^{-q}$$

Equation (1) determines a sequence of equations relating the moments and the cumulants known as the moment-cumulant relation. Below is a table giving the first few equations.

$$\begin{gathered}
\alpha_{1,1} = \kappa_{1,1} + \kappa_2 \\
\alpha_{2,1} = \kappa_{1,2} + 2\kappa_1\kappa_{1,1} + 2\kappa_3 + 2\kappa_1\kappa_2 \\
\alpha_{2,2} = \kappa_{2,2} + 4\kappa_1\kappa_{2,1} + 4\kappa_1^2\kappa_{1,1} + 4\kappa_4 + 8\kappa_1\kappa_3 + 2\kappa_2^2 + 4\kappa_1^2\kappa_2 \\
\alpha_{1,3} = \kappa_{1,3} + 3\kappa_1\kappa_{2,1} + 3\kappa_2\kappa_{1,1} + 3\kappa_1^2\kappa_{1,1} + 3\kappa_4 + 6\kappa_1\kappa_3 + 3\kappa_2^2 + 3\kappa_1^2\kappa_2 \\
\alpha_{2,3} = \kappa_{2,3} + 2\kappa_1\kappa_{1,3} + 3\kappa_1\kappa_{2,2} + 3\kappa_2\kappa_{1,2} + 9\kappa_1^2\kappa_{1,2} + 6\kappa_1\kappa_2\kappa_{1,1} + 6\kappa_1^3\kappa_{1,1} \\
+ 6\kappa_5 + 18\kappa_1\kappa_4 + 12\kappa_2\kappa_3 + 18\kappa_1^2\kappa_3 + 12\kappa_1\kappa_2^2 + 6\kappa_1^3\kappa_2 \\
\alpha_{3,3} = \kappa_{3,3} + 6\kappa_1\kappa_{2,3} + 6\kappa_2\kappa_{1,3} + 6\kappa_1^2\kappa_{1,3} + 9\kappa_1^2\kappa_{2,2} + 18\kappa_1\kappa_2\kappa_{1,2} + 18\kappa_1^3\kappa_{1,2} \\
+ 9\kappa_2^2\kappa_{1,1} + 18\kappa_1^2\kappa_2\kappa_{1,1} + 9\kappa_1^4\kappa_{1,1} + 9\kappa_6 + 36\kappa_1\kappa_5 + 27\kappa_2\kappa_4 + 54\kappa_1^2\kappa_4 \\
+ 9\kappa_3^2 + 72\kappa_1\kappa_2\kappa_3 + 36\kappa_1^3\kappa_3 + 12\kappa_2^3 + 36\kappa_1^2\kappa_2^2 + 9\kappa_1^4\kappa_2
\end{gathered}$$

We shall find it more convenient to use the combinatorial moment cumulant relation for second order cumulants given in [7, Definition 7.4].

Let us recall the combinatorial definition of free cumulants from [24, Lecture 11]. Suppose we have a sequence of multilinear functionals $(f_n)_n$ with $f_n : \mathcal{A} \times \cdots \times \mathcal{A} \to \mathbb{C}$ being n-linear. We extend this sequence to a family indexed by $\mathcal{P}(n)$, the partitions of $[n] = \{1, 2, 3, \dots, n\}$ as follows. If $V = \{i_1, \dots, i_k\} \subset [n]$ we let $f_V(a_1, \dots, a_n) = f_k(a_{i_1}, \dots, a_{i_k})$, and if $\pi = \{V_1, \dots, V_t\} \in \mathcal{P}(n)$ we define

$$f_\pi(a_1, \dots, a_n) = f_{V_1}(a_1, \dots, a_n) \cdots f_{V_t}(a_1, \dots, a_n) \tag{2}$$

We can now use this notation to define the free cumulants of a family of random variables $\{a_1, a_2, a_3, \dots\} \subset (\mathcal{A}, \phi)$. Let $NC(n) \subset \mathcal{P}(n)$ be the subset of those partitions which are non-crossing [24, Lecture 9].

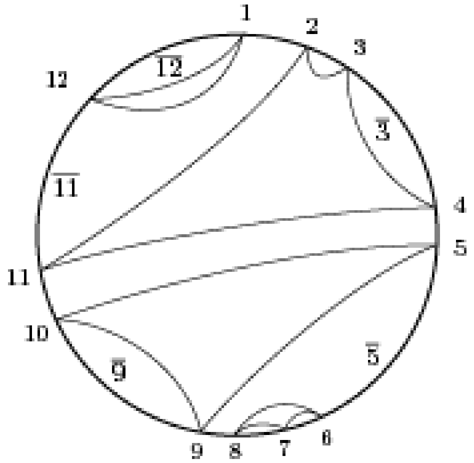

Figure 1. In this example $n_1 = 3$, $n_2 = 2$, $n_3 = 4$, $n_5 = 2$, and $n_6 = 1$. $\kappa_5(a_1a_2a_3,\ a_4a_5,\ a_6a_7a_8a_9,\ a_{10}a_{11},\ a_{12})$ will be the sum of $\kappa_\sigma(a_1, \dots, a_{12})$'s where σ runs over all σ in $NC(12)$ such that $\sigma \vee \tau_{\vec{n}} = 1_{12}$ where $\tau_{\vec{n}} = \{$ (1,2,3), (4,5), (6,7,8,9), (10, 11), (12) $\}$. This condition is equivalent to the requirement that the blocks of σ separate the points of $\{\overline{3}, \overline{5}, \overline{9}, \overline{11}, \overline{12}\}$.

Then we define multilinear functionals $(\kappa_r)_r$ implicitly by the system of equations

$$\phi(a_1a_2\cdots a_n) = \sum_{\pi \in NC(n)} \kappa_\pi(a_1, a_2, \dots, a_n) \tag{3}$$

Note that for each n this defines $\kappa_n(a_1, a_2, \dots, a_r)$ in terms of $\kappa_p(a_{i_1}, \dots, a_{i_p})$ for $p < n$ because κ_n only occurs once in equation (3), when $\pi = 1_n = \{1, 2, \dots, n\}$.

The theorem of Krawczyk and Speicher that we extend can now be stated. Let $(\mathcal{A}, \phi)$ be a non-commutative probability space and $a_1, \dots, a_{n_1}, a_{n_1+1}, \dots, a_{n_1+n_2}, \dots, a_{n_1+\cdots+n_{p-1}+1}, \dots, a_{n_1+\cdots+n_p}$ be elements of $\mathcal{A}$. Let $A_1 = a_1 \cdots a_{n_1}$, $A_2 = a_{n_1+1} \cdots a_{n_1+n_2}$, $\dots$, $A_p = a_{n_1+\cdots+n_{p-1}+1} \cdots a_{n_1+\cdots+n_p}$. The problem is to compute $\kappa_p(A_1, A_2, \dots, A_p)$ in terms of the cumulants $\kappa_\sigma(a_1, \dots, a_n)$ where $n = n_1 + n_2 + \cdots + n_p$. In [17, Theorem 2.2] it is shown that

$$\kappa_p(A_1, \dots, A_p) = \sum_{\sigma \in NC(n)} \kappa_\sigma(a_1, \dots, a_n) \tag{4}$$

where the sum is over all non-crossing partitions σ such that $\sigma \vee \tau_{\vec{n}} = 1_n$ and $\tau_{\vec{n}} = \{(1, \dots, n_1), (n_1 + 1, \dots, n_1 + n_2), \dots, (n_1 + \cdots + n_{p-1} + 1, \dots, n_1 + \cdots + n_p)\}$ and $1_n = \{(1, \dots, n)\}$ (see Figure 1).

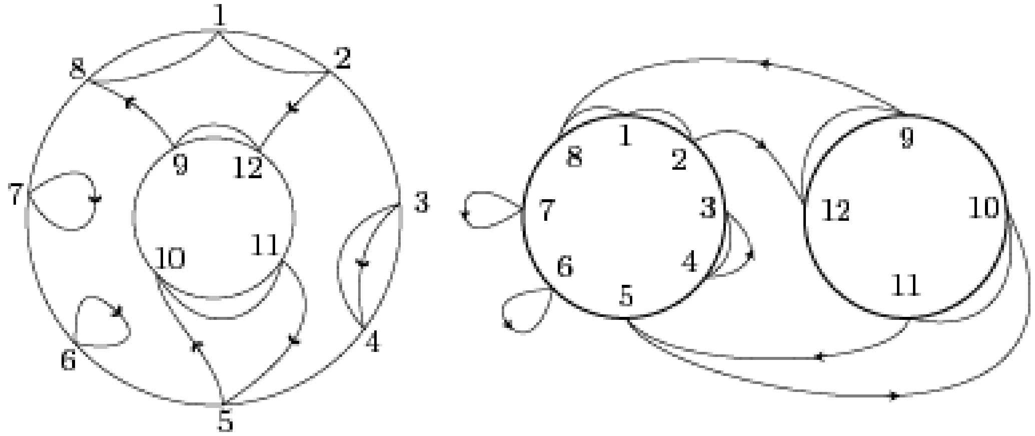

Figure 2. A non-crossing permutation of the (8,4)-annulus with cycles (1, 2, 12, 9, 8)(3, 4)(5, 10, 11)(6)(7). The same permutation redrawn with the circles side-by-side.

The main result of this paper is to prove the analogous result for second order cumulants, viz. to write $\kappa_{p,q}(A_1, \dots, A_{p+q})$ in terms of first and second order cumulants of $(a_1, \dots, a_n)$.

To describe the second order cumulants of a second order probability space $(\mathcal{A}, \phi, \phi_2)$ we need the second order equivalent of $NC(n)$. The two parts to this extension are (i) the notion of a non-crossing annular permutation (see [21, §3] and [23, §2.2]) and (ii) the notion of a non-crossing partitioned permutation (see [7, §4]).

The non-crossing annular permutations, $S_{NC}(p, q)$, were defined in [21] to be permutations π in S_{p+q}, the symmetric group $[p + q]$, which satisfy a geodesic condition.

$$\#(\pi) + \#(\pi^{-1}\gamma_{p,q}) + \#(\gamma_{p,q}) = p + q + 2 \tag{5}$$

where $\#(\pi)$ denotes the number of cycles of π and $\gamma_{p,q}$ is the permutation with the two cycles $(1, 2, 3, \dots, p)(p + 1, \dots, p + q)$. The cycles of these permutations can be drawn as non-crossing blocks of a (p, q)-annulus (see Figure 2).

The second notion that we need is that of a non-crossing partitioned permutation. The theory is developed in some generality in [7, §4] but we shall only need a particular case. Let π be a permutation in S_n and $\mathcal{V} = \{V_1, V_2, \dots, V_t\}$ be a partition of $[n]$. If each cycle of π is contained in some block of $\mathcal{V}$ then we say that $(\mathcal{V}, \pi)$ is a *partitioned permutation.* We will frequently write this informally as $\pi \leq \mathcal{V}$.

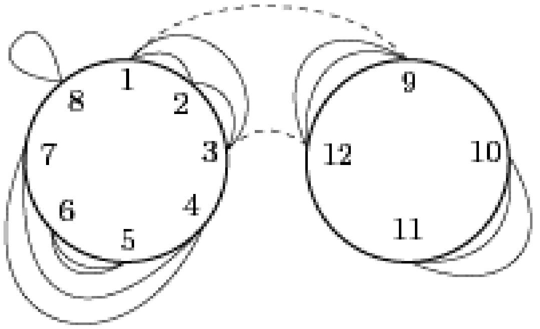

Figure 3. A non-crossing partitioned permutation $(\mathcal{V}, \pi)$ where $\pi = (1,2,3)(4,7)(5,6)(8)(9,12)(11,12)$ and $\mathcal{V} = \{V_1, V_2, V_3, V_4, V_5\}$ with $V_1 = (1,2,3,9,12)$, $V_2 = (4,7)$, $V_3 = (5,6)$, $V_4 = (8)$, and $V_5 = (10,11)$. The block V_1 contains two cycles of π — this is indicated by the dotted line in the diagram; all other blocks of $\mathcal{V}$ contain only one cycle of π.

Definition 1. Let p and q be positive integers. Given $\pi \in S_{NC}(p,q)$ we let 0_π be the partition of $[p+q]$ where the blocks of $\mathcal{V}$ are exactly the cycles of π. In this way we regard π as the partitioned permutation $(0_\pi, \pi)$. Given $\pi = \pi_1 \times \pi_2 \in NC(p) \times NC(q)$ and a partition $\mathcal{V}$ of $[p+q]$ such that $\pi \leq \mathcal{V}$ we shall say $(\mathcal{V}, \pi) \in \mathcal{PS}_{NC}(p,q)'$ if all blocks, except one, of $\mathcal{V}$ contain only one cycle of π and this exceptional block contains two cycles of π – one of π_1 and one of π_2. (See Figure 3.) We let $\mathcal{PS}_{NC}(p,q) = S_{NC}(p,q) \cup \mathcal{PS}_{NC}(p,q)'$ (*c.f.* [7, Definition 5.13]).

Next we wish to extend the definition in equation (2) to the second order case. Suppose we have two sequences $(f_n)_n$ and $(f_{p,q})_{p,q}$ of multilinear functionals on a vector space with f_r being r-linear and invariant under cyclic permutation of its arguments, and $f_{p,q}$ being $p+q$-linear and invariant under a cyclic permutation of the first p arguments or the last q arguments. Let $(\mathcal{V}, \pi)$ be a partitioned permutation where each block of $\mathcal{V}$ contains either one or two cycles of π. If V is a block of $\mathcal{V}$ containing only one cycle $(i_1, \dots, i_s)$ of π then we define $f_V(a_1, \dots, a_{p+q})$ to be $f_s(a_{i_1}, \dots, a_{i_s})$, as was done for equation (1). If V contains two cycles $(i_1, \dots, i_s)$ and $(j_1, \dots, j_t)$ of π then we define $f_V(a_1, \dots, a_{p+q})$ to be $f_{s,t}(a_{i_1}, \dots, a_{i_s}, a_{j_1}, \dots, a_{j_t})$. We then define

$$f_{(\mathcal{V},\pi)}(a_1, \dots, a_{p+q}) = f_{V_1}(a_1, \dots, a_{p+q}) \cdots f_{V_l}(a_1, \dots, a_{p+q}) \tag{6}$$

where $\mathcal{V} = \{V_1, V_2, \dots, V_l\}$.

Definition 2. Let $(\mathcal{A}, \phi, \phi_2)$ be a second order probability space and $(\kappa_n)_n$ the first order cumulants given by equation (3). We define recursively second order cumulants $(\kappa_{p,q})_{p,q}$ which will be multi-linear functionals on $\mathcal{A}$ by the system of equations

$$\phi_2(a_1 \cdots a_p, a_{p+1} \cdots a_{p+q}) = \sum_{(\mathcal{V},\pi) \in \mathcal{PS}_{NC}(p,q)} \kappa_{(\mathcal{V},\pi)}(a_1, \dots, a_{p+q}) \tag{7}$$

In equation (7) the term $\kappa_{p,q}(a_1, \dots, a_{p+q})$ only occurs once: when $\mathcal{V} = 1_{p+q}$ and $\pi = \gamma_{p,q}$ where $\gamma_{p,q}$ is the permutation with two cycles $(1, 2, \dots, p)(p+1, \dots, p+q)$. For all other $(\mathcal{V}, \pi)$, $\kappa_{(\mathcal{V},\pi)}$ is a product of κ_n's and $\kappa_{r,s}$'s with either $r < p$ or $s < q$.

It is usually convenient to write equation (7) as a sum with two terms: the first term only involves first order cumulants and the second term both orders of cumulants. Recall that $\mathcal{PS}_{NC}(p,q) = S_{NC}(p,q) \cup \mathcal{PS}_{NC}(p,q)'$ and so

$$\begin{aligned} \phi_2(a_1 \cdots a_p, a_{p+1} \cdots a_{p+q}) &= \sum_{\pi \in S_{NC}(p,q)} \kappa_\pi(a_1, \dots, a_{p+q}) \\ &\quad + \sum_{(\mathcal{V},\pi) \in \mathcal{PS}_{NC}(p,q)'} \kappa_{(\mathcal{V},\pi)}(a_1, \dots, a_{p+q}) \end{aligned} \tag{8}$$

To illustrate this definition let us work out the first few second order cumulants. When $p = q = 1$ equation (6) becomes

$$\phi_2(a, b) = \kappa_2(a, b) + \kappa_{1,1}(a, b)$$

because there are two elements in $\mathcal{PS}_{NC}(1, 1)$; the first is when $(\mathcal{V}, \pi) = (1_2, (1, 2))$ and the second when $(\mathcal{V}, \pi) = (1_2, (1)(2))$. Here we are writing the permutations in cycle notation and 1_2 is the partition of $[2]$ that has one block. By equation (3) $\kappa_2(a, b) = \phi(ab) - \phi(a)\phi(b)$. So solving for $\kappa_{1,1}(a, b)$ we obtain that

$$\kappa_{1,1}(a, b) = \phi_2(a, b) + \phi(a)\phi(b) - \phi(ab)$$

Let us next look at the case $p = 2$ and $q = 1$. There are four partitioned permutations $(\mathcal{V}, \pi)$ with $\mathcal{V} = 0_\pi$. They are $\pi_1 = (1, 3, 2)$, $\pi_2 = (1, 2, 3)$, $\pi_3 = (1, 3)(2)$ and $\pi_4 = (1)(2, 3)$. These are the four non-crossing annular permutations of a $(2, 1)$-annulus (see Figure 4).

The contributions of these four diagrams is $\kappa_3(a_1, b, a_2) + \kappa_3(a_1, a_2, b) + \kappa_2(a_1, b)\kappa_1(a_2) + \kappa_1(a_1)\kappa_2(a_2, b)$.

There are three diagrams that involve second order cumulants; they correspond to the three partitioned permutations: $(1_3, \gamma_{2,1})$, $(\mathcal{V}_1, e)$, and $(\mathcal{V}_2, e)$, where $1_3 = ((1, 2, 3))$, $\gamma_{2,1} = (1, 2)(3)$, $e = (1)(2)(3)$ is the identity permutation, $\mathcal{V}_1 = \{(1, 3), (2)\}$, and $\mathcal{V}_2 = \{(1), (2, 3)\}$ (see Figure 5).

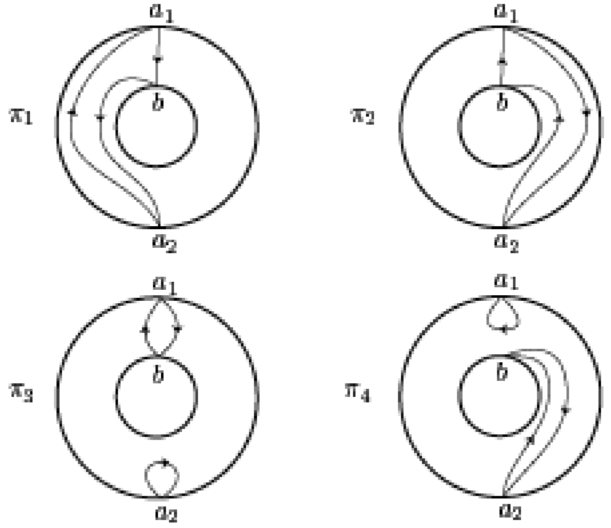

Figure 4. The four non-crossing permutations of a $(2,1)$-annulus.

The contribution of these three diagrams is $\kappa_{2,1}(a_1,a_2,b)+\kappa_{1,1}(a_1,b)\kappa_1(a_2)+\kappa_1(a_1)\kappa_{1,1}(a_2,b)$. Note that second order cumulants only appear when a block of $\mathcal{V}$ connects two cycles of π. Putting together all the terms we see that

$$\begin{aligned}\kappa_{2,1}(a_1,a_2,b) \;=\;& \phi_2(a_1a_2,b)-\phi(a_1)\phi_2(a_2,b)-\phi(a_2)\phi_2(a_1,b)\\ &-\phi(a_1a_2b)-\phi(a_1ba_2)+2\phi(a_1)\phi(a_2b)\\ &+2\phi(a_1b)\phi(a_2)+2\phi(a_1a_2)\phi(b)\\ &-4\phi(a_1)\phi(a_2)\phi(b)\end{aligned}$$

In [7, Definition 7.4] a general formula was given for writing any cumulant in terms of the moments using the higher order Möbius function. We shall prefer to use equation (7).

In equation (4) the condition on π was that $\pi \vee \tau_{\vec{r}} = 1_n$. We shall show that this is equivalent to the condition that $\pi^{-1}\gamma_n$ *separates* the points of $N=\{n_1, n_1+n_2, \dots, n_1+\cdots+n_r\}$, i.e. that no two points of N lie in the same cycle of $\pi^{-1}\gamma_n$. When we pass to the annular case this condition becomes that $\pi^{-1}\gamma_{p,q}$ separates the points of N.

Theorem 3. *Suppose* $n_1,\dots,n_r,n_{r+1},\dots,n_{r+s}$ *are positive integers,* $p=n_1+\cdots+n_r$, $q=n_{r+1}+\cdots+n_{r+s}$, *and*

$$N=\{n_1, n_1+n_2, \dots, n_1+\cdots+n_{r+s}\}$$

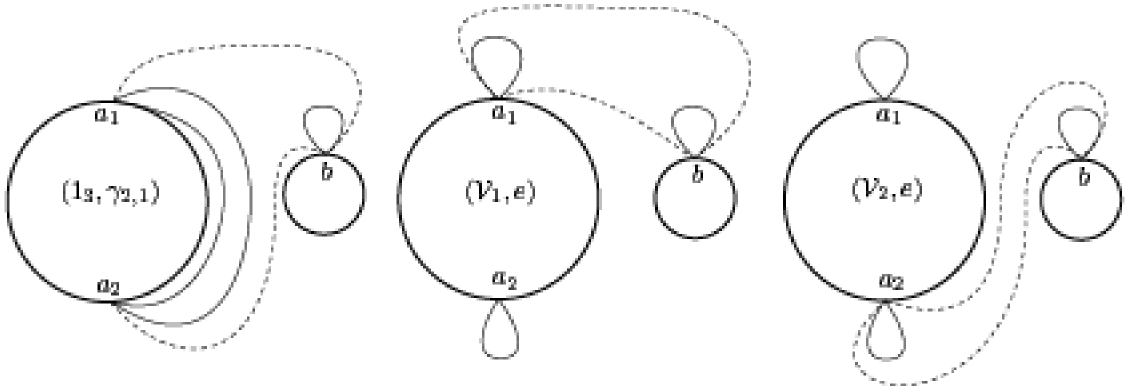

Figure 5. The three diagrams that involve second order cumulants.

Given a second order probability space $(\mathcal{A}, \phi, \phi_2)$ *and*

$$a_1, \dots, a_{n_1}, a_{n_1+1}, \dots, a_{n_1+n_2}, \dots, a_{n_1+\cdots+n_{r+s}} \in \mathcal{A}$$

Let $A_1 = a_1 \cdots a_{n_1}, \ \dots, \ A_{r+s} = a_{n_1+\cdots+n_{r+s-1}+1} \cdots a_{n_1+\cdots+n_{r+s}}$. *Then*

$$\kappa_{r,s}(A_1, \dots, A_r, A_{r+1}, \dots, A_{r+s}) = \sum_{(\mathcal{V},\pi)} \kappa_{(\mathcal{V},\pi)}(a_1, \dots, a_{p+q}) \tag{9}$$

where the summation is over those $(\mathcal{V}, \pi) \in \mathcal{PS}_{NC}(p,q)$ *such* $\pi^{-1}\gamma_{p,q}$ *separates the points of* N.

In section 2 we shall present some preliminary results on non-crossing permutations needed for the proof of the main theorem, which will appear in section 3. In section 4 we will give some examples of how the theorem can be used and concluding remarks.

2. PRELIMINARIES ON NON-CROSSING PERMUTATIONS

In this section we shall recall the notation we shall need for the proof of the main theorem and translate the criterion of equation (4) into a criterion appropriate to the annular case: Proposition 25

Notation 4. Let $\pi \in S_n$ and let $\#(\pi)$ be the number of cycles in the cycle decomposition of π. Let $\gamma_n = (1, 2, 3, \dots, n)$. We put the metric on S_n given by $|\pi| = d(e, \pi) = n - \#(\pi)$ where e is the identity permutation and $d(\pi, \sigma) = d(e, \pi^{-1}\sigma) = d(e, \sigma\pi^{-1})$. For $\pi \in S_n$ to be in $NC(n)$ it is necessary and sufficient that

$$\#(\pi) + \#(\pi^{-1}\gamma_n) + \#(\gamma_n) = n + 2$$

which is equivalent to the condition in Biane [4]

$$|\pi| + |\pi^{-1}\gamma_n| = |\gamma_n|$$

In addition, Biane showed that for π, $\sigma \in NC(n)$ the relation $\pi \leq \sigma$ is equivalent to the equation $|\pi| + |\pi^{-1}\sigma| = |\sigma|$, where the relation $\pi \leq \sigma$ means that each cycle of π is contained in some cycle of σ. Recall that with this partial order $NC(n)$ is a lattice; the supremum of two non-crossing permutations will be denoted $\pi \vee \sigma$.

For $\pi \in S_{p+q}$ to be in $S_{NC}(p, q)$ it is necessary and sufficient (see [21]) that at least one cycle of π connects the two cycles of $\gamma_{p,q}$ and

$$\#(\pi) + \#(\pi^{-1}\gamma_{p,q}) + \#(\gamma_{p,q}) = p + q + 2$$

where $\gamma_{p,q}$ is the permutation with two cycles $(1, 2, 3, \dots, p)(p+1, \dots, p+q)$. In terms of the metric this condition becomes $|\pi| + |\pi^{-1}\gamma_{p,q}| = |\gamma_{p,q}| + 2$. In [7, §4.5] a general theory of length of a partitioned permutation is given.

Let $\pi \in S_n$ and $N \subset [n]$ be a subset. If π leaves N invariant we denote by $\pi|_N$ the restriction of π to N. If π does not leave N invariant we can still define a permutation on N as follows. If $p \in N$ and $\pi(p) \notin N$ then $\pi|_N(p) = \pi^k(p)$ where k is the smallest integer such that $\pi^{k-1}(p) \notin N$ but $\pi^k(p) \in N$. Let $NC(N)$ denote the non-crossing permutations of N where the points are in the same order as they are in $[n]$. If π is in $NC(n)$ then $\pi|_N$ is in $NC(N)$, as a crossing for $\pi|_N$ would also be a crossing for π.

Let p and q be positive integers and $N \subset [p + q]$. Let $N_1 = N \cap [p]$ and $N_2 = N \cap [p+1, p+q]$. We denote by $S_{NC}(N_1, N_2)$ the non-crossing annular permutations of N arranged on an annulus with the points of N_1 on the outer circle and the points of N_2 on the inner circle.

Lemma 5. *Given $\pi \in S_{NC}(p, q)$, $\pi|_N \in S_{NC}(N_1, N_2) \cup (NC(p) \times NC(q))$.*

Proof. By [21, Equation 5.2] there are integers u and v such that $\tilde{\pi} = \gamma_p^u \gamma_q^v \pi \gamma_q^{-v} \gamma_p^{-u} \in NC(p + q)$. Let $\tilde{N} = \gamma_p^u \gamma_q^v(N)$. Then $\tilde{\pi}|_{\tilde{N}} \in NC(\tilde{N})$ and $\pi|_N$ and $\tilde{\pi}|_{\tilde{N}}$ are conjugate. Thus $\pi|_N \in S_{NC}(N_1, N_2) \cup NC(p) \times NC(q)$. □

Lemma 6. *Let N be a subset of $[n]$ and $\sigma, \pi \in S_n$ such that $\pi(i) = i$ for $i \notin N$ (and thus π leaves N invariant). Then $(\sigma\pi)|_N = \sigma|_N \, \pi|_N$.*

Proof. Let $m \in N$ and suppose $(\sigma\pi)|_N(m) = (\sigma\pi)^k(m)$. Then for $1 \leq i < k$, $\sigma^i(\pi(m)) \notin N$ and $\sigma^k(\pi(m)) \in N$. Thus $\sigma^i|_N(\pi(m)) \notin N$ for $1 \leq i < k$ and $\sigma^k(\pi(m)) \in N$. Hence $\sigma|_N(\pi(m)) = (\sigma\pi)|_N(m)$. Hence $\sigma|_N \, \pi|_N = (\sigma\pi)|_N$. □

The next lemma is a special case of [7, Proposition 4.10].

Lemma 7. *Suppose π, σ, and τ are in S_n and $|\pi| + |\pi^{-1}\sigma| = |\sigma|$ and $|\sigma| + |\sigma^{-1}\tau| = |\tau|$. Then $|\pi| + |\pi^{-1}\tau| = |\tau|$.*

In [4, Theorem 1] Biane showed that if σ has only one cycle and $|\pi| + |\pi^{-1}\sigma| = |\sigma|$ then the cycles of π form a non-crossing partition of σ. We shall need the extension of this to the case where σ has more than one cycle.

Lemma 8. *Suppose $\pi, \sigma \in S_n$ and $|\pi| + |\pi^{-1}\sigma| = |\sigma|$. Then*

i) each cycle of π is contained in some cycle of σ, and
ii) for each cycle c of σ the enclosed cycles of π form a non-crossing partition of c.

Proof. First let us show (i). Suppose that a and b are in the same cycle of π. We must show that they are in the same cycle of σ. If a and b are in the same cycle of π then writing the transposition that switches a and b as (a, b) we have $|(a, b)| + |(a, b)^{-1}\pi| = |\pi|$. Thus by Lemma 7 $|(a, b)| + |(a, b)^{-1}\sigma| = |\sigma|$; hence a and b are in the same cycle of σ.

Let us show that (ii) then follows from [4, Theorem 1].

Write $\sigma = c_1 c_2 \cdots c_k$ as a product of cycles and let π_i be the product of cycles of π contained in the cycle c_i. For each i we have $|c_i| \leq |\pi_i| + |\pi_i^{-1} c_i|$. Thus

$$\begin{aligned} |\sigma| &= |c_1| + \cdots + |c_k| \leq |\pi_1| + \cdots + |\pi_k| \\ &\qquad + |\pi_1^{-1} c_1| + \cdots + |\pi_k^{-1} c_k| = |\pi| + |\pi^{-1}\sigma| = |\sigma| \end{aligned}$$

Thus for each i we must have equality in the inequality $|c_i| \leq |\pi_i| + |\pi_i^{-1} c_i|$. Hence (ii). ☐

Definition 9. (i) Let $n_1, n_2, \ldots, n_r$ be positive integers and $n = n_1 + n_2 + \cdots + n_r$. Given a permutation $\pi \in S_r$ we shall define a permutation $\pi_{\vec{n}} \in S_n$ as follows. Let $N = \{n_1, n_1 + n_2, \ldots, n_1 + n_2 + \cdots + n_r\}$. For $i \notin N$ let $\pi_{\vec{n}}(i) = i + 1$ and $\pi_{\vec{n}}(n_1 + \cdots + n_k) = n_1 + \cdots + n_{\pi(k)-1} + 1$.
(ii) Let τ be the partition of $[r]$ in which all blocks are singletons.

This definition may be illustrated as follows. First $\tau_{\vec{n}} = \{T_1, T_2, \ldots, T_r\}$ where T_i is the cycle $(n_1 + \cdots + n_{i-1} + 1, n_1 + \cdots + n_{i-1} + 2, \ldots, n_1 + \cdots + n_i)$. $\pi_{\vec{n}}$ takes the last element of T_i to the first element of $T_{\pi(i)}$, elements not in N are increased by 1. If $\mathcal{V}$ is a partition of $[r]$, we let $\mathcal{V}_{\vec{n}} = \mathcal{V} \vee \tau_{\vec{n}}$.

Example 10. Let $n_1 = 2$, $n_2 = 3$, $n_3 = 4$ and $\pi = (1, 3)(2)$. Then $\pi_{\vec{n}} = (1, 2, 6, 7, 8, 9)(3, 4, 5)$ (see Figure 6.).

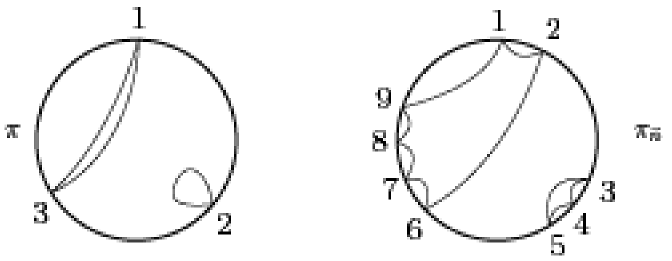

Figure 6. $\pi \in S_3$ and $\pi_{\vec{n}} \in S_9$

Remark 11. Since $\pi_{\vec{n}}$ takes the last element of T_i to the first element of $T_{\pi(i)}$, $\pi_{\vec{n}}^{-1}$ takes the first element of T_i to the last element of $T_{\pi^{-1}(i)}$. Thus

$$\pi_{\vec{n}}^{-1}\gamma_n(i) = \begin{cases} i & i \notin N \\ n_1 + \cdots + n_{\pi^{-1}(j+1)} & i = n_1 + \cdots + n_j \end{cases}$$

This last case can also be written $\pi_{\vec{n}}^{-1}\gamma_n(n_1 + \cdots + n_j) = n_1 + \cdots + n_{\pi^{-1}\gamma_r(j)}$.

Lemma 12. *Let $\psi : [r] \to [n]$ be defined by $\psi(i) = n_1 + \cdots + n_i$. Then*

i) $\psi\pi^{-1}\gamma_r = \pi_{\vec{n}}^{-1}\gamma_n\psi$
ii) $\pi \in NC(r)$ if and only if $\pi_{\vec{n}} \in NC(n)$

Proof. Part (i) follows from the previous remark. $\#(\pi) = \#(\pi_{\vec{n}})$ and $\#(\pi_{\vec{n}}^{-1}\gamma_n) = \#(\pi^{-1}\gamma_r) + n - r$, by part ($i$). Thus

$$\#(\pi_{\vec{n}}) + \#(\pi_{\vec{n}}^{-1}\gamma_n) + \#(\gamma_n) = \#(\pi) + \#(\pi_{\vec{n}}^{-1}\gamma_r) + \#(\gamma_r) + n - r$$

Hence $\#(\pi_{\vec{n}}) + \#(\pi_{\vec{n}}^{-1}\gamma_n) + \#(\gamma_n) = n + 2$ if and only if $\#(\pi) + \#(\pi^{-1}\gamma_r) + \#(\gamma_r) = r + 2$ □

Lemma 13. *Let $\tau, \sigma, \gamma \in NC(n)$ with $\tau, \sigma \leq \gamma$. Then $\tau \leq \sigma^{-1}\gamma$ if and only if $\sigma \leq \gamma\tau^{-1}$.*

Proof. If $\tau \leq \sigma^{-1}\gamma$ then $|\tau| + |\tau^{-1}\sigma^{-1}\gamma| = |\sigma^{-1}\gamma|$. Since $\sigma \leq \gamma$ we also have $|\sigma| + |\sigma^{-1}\gamma| = |\gamma|$. Thus

$$\begin{aligned} |\sigma| + |\sigma^{-1}\gamma\tau^{-1}| &= |\gamma| - |\sigma^{-1}\gamma| + |\tau^{-1}\sigma^{-1}\gamma| \\ &= |\gamma| - |\sigma^{-1}\gamma| + |\sigma^{-1}\gamma| - |\tau| \\ &= |\gamma| - |\tau| = |\gamma\tau^{-1}| \end{aligned}$$

and therefore $\sigma \leq \gamma\tau^{-1}$.

If $\sigma \leq \gamma\tau^{-1}$ then $|\sigma| + |\sigma^{-1}\gamma\tau^{-1}| = |\gamma\tau^{-1}|$; also $|\tau| + |\tau^{-1}\gamma| = |\gamma|$. Thus

$$\begin{aligned} |\tau| + |\tau^{-1}\sigma^{-1}\gamma| &= |\gamma| - |\gamma\tau^{-1}| + |\sigma^{-1}\gamma\tau^{-1}| \\ &= |\gamma| - |\gamma\tau^{-1}| + |\gamma\tau^{-1}| - |\sigma| \\ &= |\sigma^{-1}\gamma| = |\sigma^{-1}\gamma| \end{aligned}$$

which shows that $\tau \leq \sigma^{-1}\gamma$. □

Lemma 14. *For $\sigma \in NC(n)$, $\sigma \vee \tau_{\vec{n}} = \gamma_n$ if and only if $\sigma^{-1}\gamma_n$ separates the points of N*

Proof. We have $\tau_{\vec{n}}^{-1}\gamma_n(n_1 + \cdots + n_k) = n_1 + \cdots + n_{k+1}$ and thus for $r \neq s \in N$, $(r,s) \leq \tau_{\vec{n}}^{-1}\gamma_n$ and thus by the lemma above, $\tau_{\vec{n}} \leq \gamma_n(r,s)$. Hence, if $r \neq s \in N$ are in the same cycle of $\sigma^{-1}\gamma_n$ then by the lemma above $\sigma \leq \gamma_n(r,s)$ and hence $\sigma \vee \tau_{\vec{n}} \leq \gamma_n(r,s)$.

Conversely if $\sigma \vee \tau_{\vec{n}} < \gamma_n$ then there must be $r \neq s \in N$ such that $\sigma \vee \tau_{\vec{n}} \leq \gamma_n(r,s)$, as partitions of the form $\gamma_n(r,s)$ with $r \neq s \in N$ are the most general partitions with two blocks, each of which is a union of T_i's. In this case $(r,s) \leq \sigma^{-1}\gamma_n$ and $\sigma^{-1}\gamma_n$ fails to separate the points of N. □

Theorem 15. *For $\sigma \in NC(n)$ with $\sigma \leq \pi_{\vec{n}}$ we have that $\sigma \vee \tau_{\vec{n}} = \pi_{\vec{n}}$ if and only if $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N.*

Proof. Let the cycle decomposition of π be $c_1\, c_2 \cdots c_k$. Then the cycle decomposition of $\pi_{\vec{n}}$ is $\tilde{c}_1\, \tilde{c}_2 \cdots \tilde{c}_k$ where $\tilde{c}_i = (c_i)_{\vec{n}}$. Let σ_i be the restriction of σ to the invariant subset consisting of the points of the cycle $\tilde{c}_i$; and similarly let τ_i be the restriction of $\tau_{\vec{n}}$ to the same invariant subset. Thus $\sigma \vee \tau_{\vec{n}} = \pi_{\vec{n}}$ if and only if for each i we have $\sigma_i \vee \tau_i = \tilde{c}_i$, and by the previous lemma we have that $\sigma_i \vee \tau_i = \tilde{c}_i$ for each i if and only if for each i, $\sigma_i^{-1}\tilde{c}_i$ separates the points of $N \cap \tilde{c}_i$. Since for each i, $\pi_{\vec{n}}$, σ, and $\tau_{\vec{n}}$ leave $\tilde{c}_i$ invariant, we have that $\sigma^{-1}\pi_{\vec{n}}$ separates the points of $N \cap \tilde{c}_i$ for each i if and only if $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N. □

Remark 16. The condition that $\sigma^{-1}\gamma_n$ separates the points of N can be rephrased as saying that any two points in the same cycle of $\tau_{\vec{n}}^{-1}\gamma_n$ must be in different cycles of $\sigma^{-1}\pi_{\vec{n}}$.

Definition 17. Let $\pi, \sigma \in S_{NC}(p,q)$. Suppose that each cycle of π is contained in some cycle of σ and for each cycle c of σ the enclosed cycles of π form a non-crossing partition of c. Then we write $\pi \leq \sigma$. By Lemma 8 this relation extends to $S_{NC}(p,q)$ the usual partial order on $NC(n)$ given by inclusion of blocks.

Remark 18. We can rephrase the definition above using our metric d. Write the cycles of π as $c_1 c_2 \cdots c_l$ and denote the restriction of π to c_i by π_i. Then we have

$$\#(\pi_i) + \#(\pi_i^{-1} c_i) + \#(c_i) = k_i + 2$$

where k_i is the length of the cycle c_k. If we sum over i we get

$$\#(\pi) + \#(\pi^{-1}\sigma) + \#(\sigma) = p + q + 2l$$

which can be rewritten $|\pi| + |\pi^{-1}\sigma| = |\sigma|$ (c.f. [7, Definition 4.9]). That the relation $\leq$ is transitive follows from [7, Proposition 4.10], or in this simple case can be checked directly.

Moreover, we can extend the Definition 17 as follows. Suppose that $\pi \in S_{p+q}$, $\sigma \in S_{NC}(p,q)$ and each cycle of π is contained in a cycle of σ and for each cycle of σ the enclosed cycles of π form a non-crossing permutation of this cycle of σ. By [21, Equation 5.2] there are integers u and v such that $\tilde{\sigma} = \gamma_p^u \gamma_q^v \sigma \gamma_q^{-v} \gamma_p^{-u} \in NC(p+q)$. Let $\tilde{\pi} = \gamma_p^u \gamma_q^v \pi \gamma_q^{-v} \gamma_p^{-u}$. Then each cycle of $\tilde{\pi}$ is contained in a cycle of $\tilde{\sigma}$ and for each cycle of $\tilde{\sigma}$ the enclosed cycles of $\tilde{\pi}$ form a non-crossing partition. Thus $\tilde{\pi}$ is non-crossing and $\tilde{\pi} \leq \tilde{\sigma}$. Hence $\pi \in (NC(p) \times NC(q)) \cup S_{NC}(p,q)$. This discussion shows that the partial order $\leq$ could also have been defined as

i) each cycle of π is contained in some cycle of σ; and
ii) whenever we have integers u and v such that $\gamma_p^u \gamma_q^v \sigma \gamma_q^{-v} \gamma_p^{-u} \in NC(p+q)$ we also have $\gamma_p^u \gamma_q^v \pi \gamma_q^{-v} \gamma_p^{-u} \in NC(p+q)$.

Lemma 19. *Suppose $\pi, \sigma \in S_{NC}(p,q)$ with $\pi \leq \sigma^{-1}\gamma_{p,q}$. Then $\sigma \leq \gamma_{p,q}\pi^{-1}$.*

Proof. Since $\pi, \sigma \in S_{NC}(p,q)$ we have $|\pi| + |\pi^{-1}\gamma_{p,q}| = |\gamma_{p,q}| + 2$ and $|\sigma| + |\sigma^{-1}\gamma_{p,q}| = |\gamma_{p,q}| + 2$. By hypothesis we have $|\pi| + |\pi^{-1}\sigma^{-1}\gamma_{p,q}| = |\sigma^{-1}\gamma_{p,q}|$. Thus

$$\begin{aligned} |\sigma| + |\sigma^{-1}\gamma_{p,q}\pi^{-1}| &= |\gamma_{p,q}| + 2 - |\sigma^{-1}\gamma_{p,q}| + |\sigma^{-1}\gamma_{p,q}| - |\pi| \\ &= |\gamma_{p,q}| + 2 - |\pi| = |\pi^{-1}\gamma_{p,q}| = |\gamma_{p,q}\pi^{-1}| \end{aligned}$$

□

In [7, Definition 4.9] we defined a product for partitioned permutations which we shall recall here. If $\mathcal{V}$ is a partition of $[n]$ then $|\mathcal{V}| = n - \#(\mathcal{V})$ where $\#(\mathcal{V})$ is the number of blocks of $\mathcal{V}$. If $(\mathcal{V}, \pi)$ is a partitioned permutation then $|(\mathcal{V}, \pi)| = 2|\mathcal{V}| - |\pi|$. If $(\mathcal{V}, \pi)$ and $(\mathcal{U}, \sigma)$ are partitioned permutations then they have a product if $|(\mathcal{V}, \pi)| + |(\mathcal{U}, \sigma)| = |(\mathcal{V} \vee \mathcal{U}, \pi\sigma)|$ and we write this as $(\mathcal{V}, \pi) \cdot (\mathcal{U}, \sigma) = (\mathcal{V} \vee \mathcal{U}, \pi\sigma)$; otherwise the product is not defined.

If $\sigma \in S_{p+q}$ and σ has a cycle that connects the two cycles of $\gamma_{p,q}$ then $\sigma \in S_{NC}(p,q)$ if and only if $|\sigma| + |\sigma^{-1}\gamma_{p,q}| = |\gamma_{p,q}| + 2$. In terms of partitioned permutations this means $(0_\sigma, \sigma) \cdot (0_{\sigma^{-1}\gamma_{p,q}}, \sigma^{-1}\gamma_{p,q}) = (1_{p+q}, \gamma_{p,q})$, as requiring $1_{p+q} = 0_\sigma \vee 0_{\sigma^{-1}\gamma_{p,q}}$ means that σ has a cycle that connects the two cycles of $\gamma_{p,q}$.

Lemma 20. *Suppose that* $\pi \in NC(p) \times NC(q)$ *and* $\sigma \in S_{NC}(p,q)$ *with* $\pi \leq \sigma^{-1}\gamma_{p,q}$. *Then*

$$(0_\sigma, \sigma) \cdot (0_{\sigma^{-1}\gamma_{p,q}\pi^{-1}}, \sigma^{-1}\gamma_{p,q}\pi^{-1}) = (\sigma \vee \gamma_{p,q}\pi^{-1}, \gamma_{p,q}\pi^{-1})$$

Proof. Since $\pi \leq \sigma^{-1}\gamma_{p,q}$ we have $|\pi| + |\pi^{-1}\sigma^{-1}\gamma_{p,,q}| = |\sigma^{-1}\gamma_{p,q}|$. Since $\pi \in NC(p) \times NC(q)$ we have $|\pi| + |\pi^{-1}\gamma_{p,q}| = |\gamma_{p,q}|$ and since $\sigma \in S_{NC}(p,q)$ we have $|\sigma| + |\sigma^{-1}\gamma_{p,q}| = |\gamma_{p,q}| + 2$. Thus

$$\begin{aligned}|(0_\sigma, \sigma)| + |(0_{\sigma^{-1}\gamma_{p.q}\pi^{-1}}, \sigma^{-1}\gamma_{p,q}\pi^{-1})| &= |\sigma| + |\sigma^{-1}\gamma_{p,q}\pi^{-1}| \\ = |\gamma_{p,q}| + 2 - |\sigma^{-1}\gamma_{p,q}| + |\sigma^{-1}\gamma_{p,q}| - |\pi| &= |\gamma_{p,q}\pi^{-1}| + 2\end{aligned}$$

also

$$|(\sigma \vee \gamma_{p,q}\pi^{-1}, \gamma_{p,q}\pi^{-1})| = 2|\sigma \vee \gamma_{p,q}\pi^{-1}| - |\gamma_{p,q}\pi^{-1}|$$

so we must show that $|\sigma \vee \gamma_{p,q}\pi^{-1}| = |\gamma_{p,q}\pi^{-1}| + 1$ i.e that $\sigma \vee \gamma_{p,q}\pi^{-1}$ joins two cycles of $\gamma_{p,q}\pi^{-1}$ and the cycles lie on different circles. To achieve this we shall show that if we write $\pi = \pi_1 \times \pi_2 \in NC(p) \times NC(q)$ then all through cycles of σ meet only one cycle of $\gamma_p\pi_1^{-1}$.

Indeed, suppose that two cycles c and c' of $\gamma_p\pi_1^{-1}$ meet through blocks of σ. Let $a, b \in c$ be respectively the first and last elements of c (since the cycles do not cross this is well defined). Then a and b are in the same cycle of $\gamma_{p,q}\pi^{-1}$. Thus $(\gamma_{p,q}^{-1}(a), b) \leq \pi \leq \sigma^{-1}\gamma_{p,q}$. Hence either

i) as a partition $\sigma \leq \{(a, \gamma_{p,q}(a), \dots, b, p+1, \dots, p+q), (\gamma_{p,q}(b), \dots, \gamma_{p,q}^{-1}(a))\}$ or

ii) as a partition $\sigma \leq \{(a, \gamma_{p,q}(a), \dots, b), (\gamma_{p,q}(b), \dots, \gamma_{p,q}^{-1}(a), p+1, \dots, p+q)\}$

depending on whether the through blocks of σ meet the cyclic interval $(a, \dots, b)$ or the cyclic interval $(\gamma_{p,q}(b), \dots, \gamma_{p,q}^{-1}(a))$. Since $c \subset (a, b)$ and $c' \subset (\gamma_{p,q}(b), \dots, \gamma_{p,q}^{-1}(a))$ it is impossible for both c and c' to meet thorough blocks of σ. □

Corollary 21. *Given the hypotheses of Lemma 20 we have*

i) every cycle of σ*, which is not a through cycle, is contained in a cycle of* $\gamma_{p,q}\pi^{-1}$*;*

ii) there are two cycles of $\gamma_{p,q}\pi^{-1}$*, one from each circle, and all the through cycles of* σ *are contained in the union of these two cycles;*

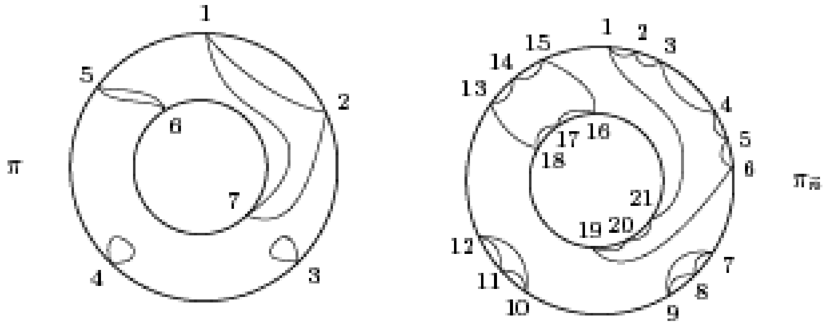

Figure 7. $\pi = (1,2,6)(3)(4)(5,6) \in S_{NC}(5,2)$, all n_i's equal to 3, and $\pi_{\vec{n}} = (1,2,3,4,5,6,19,20,21)(7,8,9)(10,11,12)(13, 14,15,16,17,18)$.

iii) for each cycle of $\gamma_{p,q}\pi^{-1}$ that does not meet a through cycle of σ the enclosed cycles of σ form a non-crossing permutation of this cycle of $\gamma_{p,q}\pi^{-1}$;

iv) the through cycles of σ form a non-crossing annular permutation of the union of the two cycles of $\gamma_{p,q}\pi^{-1}$ in (ii) above.

Notation 22. Let $n_1, n_2, \ldots, n_{r+s}$ be positive integers and let $p = n_1 + n_2 + \cdots + n_r$ and $q = n_{r+1} + \cdots + n_{r+s}$. Let $N = \{n_1, n_1+n_2, \ldots, n_1+\cdots+n_{r+s}\}$. Given $\pi \in S_{r+s}$ we define $\pi_{\vec{n}} \in S_{p+q}$ as was done in Definition 9: for $i \notin N$ $\pi_{\vec{n}}(i) = i+1$ and $\pi_{\vec{n}}(n_1 + \cdots + n_k) = n_1 + \cdots + n_{\pi(k)-1} + 1 = n_1 + \cdots + n_{\gamma_{r+s}^{-1}\pi(k)} + 1$. Then $\pi_{\vec{n}}^{-1}\gamma_{p,q}(n_1 + \cdots + n_k) = n_1 + \cdots + n_{\pi^{-1}\gamma_{r,s}(k)}$.

Lemma 23. *If $\pi \in S_{NC}(r,s)$ then $\pi_{\vec{n}} \in S_{NC}(p,q)$.*

Proof. Let $\psi : [r+s] \to [p+q]$ be given by $\psi(i) = n_1 + \cdots + n_i$. Then as in Lemma 12 we have $\psi\pi^{-1}\gamma_{r,s} = \pi_{\vec{n}}^{-1}\gamma_{p,q}\psi$. Thus

$$\begin{aligned} &\#(\pi_{\vec{n}}) + \#(\pi_{\vec{n}}^{-1}\gamma_{p,q}) + \#(\gamma_{p,q}) \\ &\quad = \#(\pi) + \#(\pi^{-1}\gamma_{r,s}) + p + q - (r+s) + \#(\gamma_{r,s}) = p + q + 2 \end{aligned}$$

□

Proposition 24. *Let $\pi \in S_{NC}(r,s)$ and $\pi_{\vec{n}} \in S_{NC}(p,q)$. If $\sigma \in S_{p+q}$ is such that*

i) each cycle of σ is contained in some cycle of $\pi_{\vec{n}}$;

ii) for each cycle of $\pi_{\vec{n}}$ the enclosed cycles of σ form a non-crossing permutation (see Figure 8); and

iii) for each cycle $\tilde{c}_i$ of $\pi_{\vec{n}}$ we have $\sigma_i \vee \tau_i = \tilde{c}_i$, where σ_i and τ_i are the respective restrictions of σ and $\tau_{\vec{n}}$ to $\tilde{c}_i$,

then $\sigma \in S_{NC}(p,q)$ and $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N.

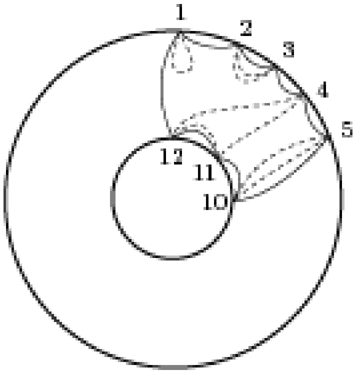

Figure 8. A cycle of a non-crossing annular permutation π and, in dotted lines, the enclosed cycles of a σ with $\sigma \leq \pi$.

Proof. From the remark above $\sigma \in (NC(p) \times NC(q)) \cup S_{NC}(p,q)$. From the theorem above $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N. Since π has a through block (i.e. a cycle that connects the two circles) there are $k_1, l_2 \leq p$ and $k_2, l_1 > p$ all in the same cycle of π, so that $\pi(k_1) = l_1$ and $\pi(k_2) = l_2$. Then $\pi_{\vec{n}}(n_1 + \cdots + n_{k_1}) = n_1 + \cdots n_{l_1 - 1} + 1$ and $\pi_{\vec{n}}(n_1 + \cdots + n_{k_2}) = n_1 + \cdots n_{l_2 - 1} + 1$. Let $\tilde{c}_i$ be the cycle of $\pi_{\vec{n}}$ containing $n_1 + cdotsn_{k_1}$ and hence $n_1 + \cdots n_{k_2}$. Since $\sigma^{-1}\tilde{c}_i$ separates the points of $N \cap \tilde{c}_i$, $n_1 + \cdots + n_{k_1}$ and $n_1 + \cdots + n_{k_2}$ must be in different cycles of $\sigma^{-1}\tilde{c}_i$, hence by Lemma 13, $\sigma_i \not\leq \tilde{c}_i(n_1 + \cdots + n_{k_1}, n_1 + \cdots + n_{k_2}) = d_1 d_2$ where the points on the cycle d_1 are contained in $[p]$ and those of d_2 in $[p+1, p+q] = \{p+1, \ldots, p+q\}$. Thus σ_i has a through block, and so $\sigma \in S_{NC}(p,q)$. ☐

Our last step in this section is to translate the criterion of equation (4) to the annular case. We suppose we have $a_1, \ldots, a_{p+q} \in \mathcal{A}$ and we let $A_1 = a_1 \cdots a_{n_1}, \ldots A_{r+s} = a_{n_1 + \cdots + n_{r+s-1} + 1} \cdots a_{n_1 + \cdots + n_{r+s}}$.

Proposition 25. *Let $\pi \in S_{NC}(r,s)$ and $\pi_{\vec{n}} \in S_{NC}(p,q)$. Then*

$$\kappa_\pi(A_1, \ldots, A_{r+s}) = \sum_{\sigma \in S_{NC}(p,q)} \kappa_\sigma(a_1, \ldots, a_{p+q})$$

where the sum is over all σ such that $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N.

Proof. Let $c_1\, c_2 \cdots c_k$ be the cycle decomposition of π and $\tilde{c}_1\, \tilde{c}_2 \cdots \tilde{c}_k$ the corresponding cycle decomposition of $\pi_{\vec{n}}$, as in the proof of Theorem 15. Using the notation of equation (2)

$$\kappa_\pi(A_1, \ldots, A_{r+s}) = \kappa_{c_1}(A_1, \ldots, A_{r+s}) \cdots \kappa_{c_k}(A_1, \ldots, A_{r+s})$$

By equation (4)

$$\kappa_{c_i}(A_1, \ldots, A_{r+s}) = \sum_{\sigma_i} \kappa_{\sigma_i}(a_1, \ldots, a_{p+q})$$

where σ_i runs over all non-crossing partitions of the point set of the cycle $\tilde{c}_i$ such that $\sigma_i \vee \tau_i = \tilde{c}_i$ (using the notation of Theorem 15), or equivalently that $\sigma_i^{-1}\tilde{c}_i$ separates the points of $N \cap \tilde{c}_i$. Thus

$$\kappa_\pi(A_1, \ldots, A_{r+s}) = \sum_{\sigma_1} \cdots \sum_{\sigma_k} \kappa_{\sigma_1}(a_1, \ldots, a_{p+q}) \cdots \kappa_{\sigma_k}(a_1, \ldots, a_{p+q})$$

where for each i, σ_i runs over the non-crossing partitions of $\tilde{c}_i$ such that $\sigma_i^{-1}\tilde{c}_i$ separates the points of $N \cap \tilde{c}_i$. Multiplying the σ_i's together we obtain all the σ's satisfying the hypotheses of Proposition 24. Thus the sum is over all $\sigma \in S_{NC}(p, q)$ such that $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N. □

3. PROOF OF THE MAIN THEOREM

Throughout this section we shall assume that we are given positive integers $n_1, n_2, \ldots, n_{r+s}$ and elements $a_1, \ldots, a_{n_1+\cdots+n_{r+s}} \in \mathcal{A}$, where $(\mathcal{A}, \phi, \phi_2)$ is a second order non-commutative probability space. We let $N = \{n_1, n_1 + n_2, \ldots, n_1 + \cdots + n_{r+s}\}$, $p = n_1 + \cdots + n_r$, $q = n_{r+1} + \cdots + n_{r+s}$, and $N_1 = [p] \cap N$ and $N_2 = N \cap [p+1, p+q]$. We let $A_1 = a_1 \cdots a_{n_1}$, ..., $A_{r+s} = a_{n_1+\cdots+n_{r+s-1}+1} \cdots a_{n_1+\cdots+n_{r+s}}$.

We shall prove Theorem 3 by induction on (r, s). So to begin let us prove the theorem when $r = s = 1$.

Lemma 26.

$$\begin{aligned}\kappa_{1,1}(a_1 \cdots a_p, a_{p+1} \cdots a_{p+q}) &= \sum_{\sigma \in S_{NC}(p,q)} \kappa_\sigma(a_1, \ldots, a_{p+q}) \\ &\quad + \sum_{(\mathcal{U},\sigma)} \kappa_{(\mathcal{U},\sigma)}(a_1, \ldots, a_{p+q})\end{aligned}$$

where in the first sum σ is such that p and $p+q$ are in different cycles of $\sigma^{-1}\gamma_{p,q}$ and in the second sum $(\mathcal{U}, \sigma)$ runs over $\mathcal{PS}_{NC}(p, q)'$.

Proof. We have two expressions for $\phi_2(a_1 \cdots a_p, a_{p+1} \cdots a_{p+q})$. The first is

$$\begin{aligned}\phi_2(a_1 \cdots a_p, a_{p+1} \cdots a_{p+q}) &= \sum_{\sigma \in S_{NC}(p,q)} \kappa_\sigma(a_1, \ldots, a_{p+q}) \\ &\quad + \sum_{(\mathcal{U},\sigma) \in \mathcal{PS}_{NC}(p,q)'} \kappa_{(\mathcal{U},\sigma)}(a_1, \ldots, a_{p+q})\end{aligned}$$

and the second is

$$\begin{aligned}\phi_2(a_1\cdots a_p, a_{p+1}\cdots a_{p+q}) &= \kappa_2(a_1\cdots a_p, a_{p+1}\cdots a_{p+q}) \\ &\quad + \kappa_{1,1}(a_1\cdots a_p, a_{p+1}\cdots a_{p+q})\end{aligned}$$

Combining these two with equation (4) we have

$$\kappa_{1,1}(a_1\cdots a_p, a_{p+1}\cdots a_{p+q}) = \sum_{\sigma\in S_{NC}(p,q)} \kappa_\sigma(a_1,\dots,a_{p+q}) \\ - \sum_{\sigma\in NC(p+q)} \kappa_\sigma(a_1,\dots a_{p+q}) + \sum_{(\mathcal{U},\sigma)} \kappa_{(\mathcal{U},\sigma)}(a_1,\dots,a_{p+q}) \tag{10}$$

where the second sum, by Lemma 14, is over $\sigma\in NC(p+q)$ such that p and $p+q$ are in different cycles of $\sigma^{-1}\gamma_{p+q}$.

Now each $\sigma\in NC(p+q)$ such that p and $p+q$ are in different cycles of $\sigma^{-1}\gamma_{p+q}$ must have a through block by Lemma 13 (i.e. a block connecting a point in $[p]$ to one in $[p{+}1, p{+}q]$) and thus by [21, Equation 5.2] is a also a non-crossing (p,q)-annular permutation. Finally since $\sigma^{-1}\gamma_{p,q} = \sigma^{-1}\gamma_{p+q}(p, p+q)$, we have that p and $p+q$ are in the same cycle of $\sigma^{-1}\gamma_{p,q}$. Hence the σ's in the second sum are exactly those in $S_{NC}(p,q)$ for which p and $p+q$ are in the same cycle of $\sigma^{-1}\gamma_{p,q}$. Removing these from the first sum we are left with the σ's for which p and $p+q$ are in different cycles of $\sigma^{-1}\gamma_{p,q}$.

Note that for the term

$$\sum_{(\mathcal{U},\sigma)} \kappa_{(\mathcal{U},\sigma)}(a_1,\dots,a_{p+q})$$

$\sigma=\sigma_1\times\sigma_2\in NC(p)\times NC(q)$ so that the condition that p and $p+q$ are in different cycles of $\sigma^{-1}\gamma_{p,q}=\sigma_1^{-1}\gamma_p\times\sigma_2\gamma_q$ is automatically satisfied.

□

In order to give an inductive proof of our main theorem we shall need an extension of its statement to the case of partitioned permutations.

Lemma 27. *Suppose that Equation (9) holds for $r'\le r$ and $s'\le s$. Then for $(\mathcal{V},\pi)\in\mathcal{PS}_{NC}(r,s)'$ we have*

$$\kappa_{(\mathcal{V},\pi)}(A_1,\dots,A_{r+s}) = \sum_{\sigma\in S_{NC}(p,q)} \kappa_\sigma(a_1,\dots,a_{p+q}) + \sum_{(\mathcal{U},\sigma)} \kappa_{(\mathcal{U},\sigma)}(a_1,\dots,a_{p+q})$$

where the first sum is over all σ's such that $\sigma\le\mathcal{V}_{\vec{n}}$ (i.e. each cycle of σ is contained in a block of $\mathcal{V}_{\vec{n}}$) and $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N, and the second sum is over all $(\mathcal{U},\sigma)$ such that $\mathcal{U}\le\mathcal{V}_{\vec{n}}$ and $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N.

Proof. Let us write π as a product of cycles: $c_1 \cdots c_k c' c''$ where the cycles $c_1, \ldots, c_k$ are the cycles of π that are the only cycle in the block of $\mathcal{V}$ that contains them and c' and c'' are the two cycles of π that lie in a single block of $\mathcal{V}$. Let $1_{c' \cup c''}$ be this block of $\mathcal{V}$ that contains the two cycles c' and c''. Then by Equation (9)

$$\begin{aligned}\kappa_{(\mathcal{V},\pi)}(A_1, \ldots, A_{r+s}) &= \kappa_{c_1}(A_1, \ldots, A_{r+a}) \cdots \kappa_{c_k}(A_1, \ldots, A_{r+s}) \\ &\quad \times \kappa_{(1_{c' \cup c''}, c'c'')}(A_1, \ldots, A_{r+s}) \\ &= \sum_{\sigma_1, \ldots, \sigma_k} \kappa_{\sigma_1}(a_1, \ldots, a_{p+q}) \cdots \kappa_{\sigma_k}(a_1, \ldots, a_{p+q}) \\ &\quad \times \Big\{ \sum_{\sigma_0} \kappa_{\sigma_0}(a_1, \ldots, a_{p+q}) + \sum_{(\mathcal{U}_0, \sigma_{00})} \kappa_{(\mathcal{U}_0, \sigma_{00})}(a_1, \ldots, a_{p+q}) \Big\}\end{aligned}$$

where σ_i runs over $NC(\tilde{c}_i)$ such that $\sigma^{-1}\tilde{c}_i$ separates the points of $N \cap \tilde{c}_i$; σ_0 runs over $S_{NC}(\tilde{c}', \tilde{c}'')$ such that $\sigma_0^{-1}\tilde{c}'\tilde{c}''$ separates the points of $N \cap 1_{\tilde{c}' \cup \tilde{c}''}$; and $(\mathcal{U}_0, \sigma_{00})$ runs over $\mathcal{PS}_{NC}(\tilde{c}', \tilde{c}'')$ such that $\sigma_{00}^{-1}\tilde{c}'\tilde{c}''$ separates the points of $N \cap 1_{\tilde{c}' \cup \tilde{c}''}$. The product $\sigma_0 \sigma_1 \cdots \sigma_k$ thus runs over $\sigma \in S_{NC}(p, q)$ such that $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N and $\sigma \leq \mathcal{V}_{\vec{n}}$. The product $(\mathcal{U}_0, \sigma_{00})\sigma_1 \cdots \sigma_k$ runs over $(\mathcal{U}, \sigma) \in \mathcal{PS}_{NC}(p, q)'$ such that $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N and $\mathcal{U} \leq \mathcal{V}_{\vec{n}}$. This proves our assertion. □

In the next lemma we consider $\sigma \in S_{NC}(p, q)$ such that $\sigma^{-1}\gamma_{p,q}$ *fails* to separate the points of N, we wish to determine $\pi \in S_{NC}(r, s)$ such that $\pi_{\vec{n}}$ will behave like the supremum of σ and $\tau_{\vec{n}}$ in that with respect to $\pi_{\vec{n}}$, σ will satisfy the three conditions of Proposition 24.

Lemma 28. *Let $\sigma \in S_{NC}(p, q)$ be such that $\sigma^{-1}\gamma_{p,q}$ has a cycle that meets both $N_1 = N \cap [n]$ and $N_2 = N \cap [p + 1, p + q]$. Then there is a unique $\pi \in S_{NC}(r, s)$ such that relative to π, σ satisfies the three conditions of Proposition 24.*

Proof. Let us first deal with uniqueness. Suppose $\pi \in S_{NC}(r, s)$ is such that $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N. Then $(\sigma^{-1}\pi_{\vec{n}})|_N = id_N$ and for $i \notin N$, $\pi_{\vec{n}}^{-1}\gamma_{p,q}(i) = i$. Thus by Lemma 6, $(\sigma^{-1}\gamma_{p,q})|_N = (\sigma^{-1}\pi_{\vec{n}})|_N \cdot (\pi_{\vec{n}}^{-1}\gamma_{p,q})|N = (\pi_{\vec{n}}^{-1}\gamma_{p,q})|_N$. Since $\pi_{\vec{n}}^{-1}\gamma_{p,q}\psi = \psi\pi^{-1}\gamma_{r,s}$ by Lemma 23, π is uniquely determined by $(\sigma^{-1}\gamma_{p,q})|_N$.

To show existence consider $(\sigma^{-1}\gamma_{p,q})|_N$. By Lemma 6, $(\sigma^{-1}\gamma_{p,q})|_N \in S_{NC}(N_1, N_2) \cup (NC(N_1) \times NC(N_2))$. By assumption, $\sigma^{-1}\gamma_{p,q}$ has a cycle meeting both N_1 and N_2; thus $(\sigma^{-1}\gamma_{p,q})|_N \in S_{NC}(N_1, N_2)$. Then there is $\pi \in S_{NC}(r, s)$ such that $\psi\pi^{-1}\gamma_{r,s}\psi^{-1} = (\sigma^{-1}\gamma_{p,q})|_N$.

Now $\pi_{\vec{n}}^{-1}\gamma_{p,q}(i) = i$ for $i \notin N$ and $\pi_{\vec{n}}^{-1}\gamma_{p,q}|_N = \sigma^{-1}\gamma_{p,q}|_N$ together imply that $\pi_{\vec{n}}^{-1}\gamma_{p,q} \leq \sigma^{-1}\gamma_{p,q}$ and thus by Lemma 19, $\sigma \leq \pi_{\vec{n}}$ and

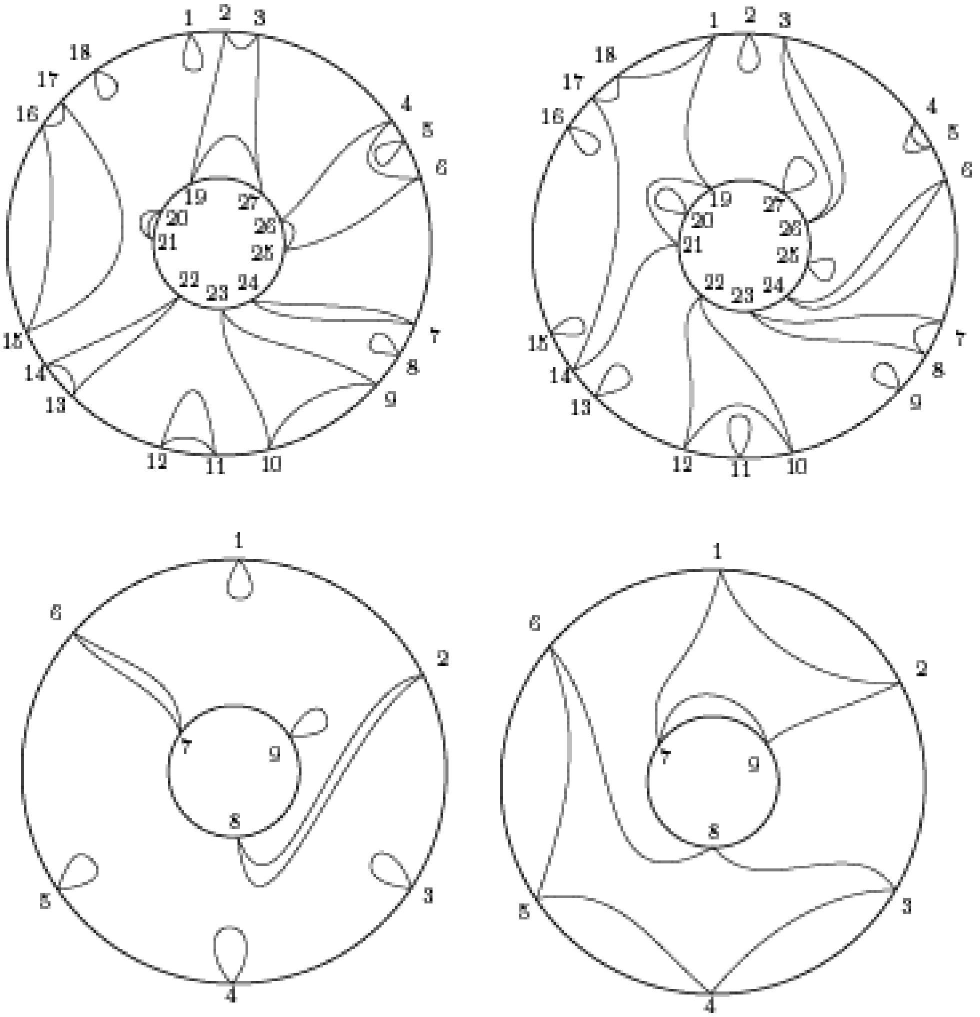

Figure 9. Shown is $\sigma \in S_{NC}(18, 9)$ in the upper left, $\sigma^{-1}\gamma_{18,9}$ in the upper right. In the lower left we have $\pi^{-1}\gamma_{6,3}$ and the lower right we have $\pi \in S_{NC}(6, 3)$. $\pi_{\vec{n}}$ is shown overleaf. Note that when $N = \{3, 6, 9, 12, 15, 18, 21, 24, 27\}$, σ satisfies the hypotheses of Lemma 28, for example 6 and 24 are in the same cycle of $\sigma^{-1}\gamma_{18,9}|_N$. The resulting $\pi^{-1}\gamma_{6,3}$ has 2 and 8 in the same cycle and thus $\pi \in S_{NC}(6, 3)$.

the cycles of σ form a non-crossing partition of those of $\pi_{\vec{n}}$. Finally by applying Lemma 14 to each cycle of $\pi_{\vec{n}}$ we obtain that the three conditions of Proposition 24 are satisfied. See Figure 9. □

Lemma 29. *Suppose that $\sigma \in S_{NC}(p, q)$ is such that $\sigma^{-1}\gamma_{p,q}$ does not separate the points of N but no cycle of $\sigma^{-1}\gamma_{p,q}$ meets both N_1 and N_2.*

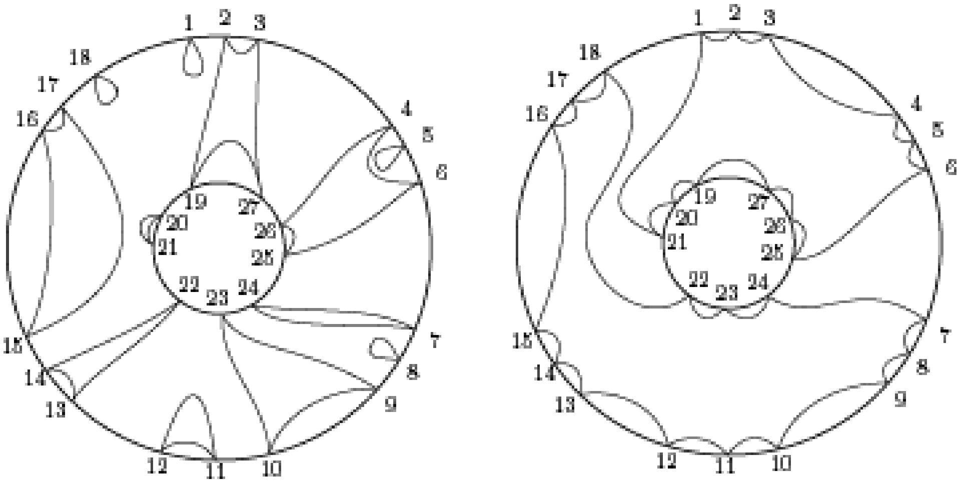

Figure 10. σ (left) from Figure 9 is compared with the $\pi_{\vec{n}} \in S_{NC}(18, 9)$ produced by Lemma 28.

Then there is a unique $(\mathcal{V}, \pi) \in \mathcal{PS}_{NC}(r, s)$ *such that* $\mathcal{V}_{\vec{n}} = \sigma \vee \tau_{\vec{n}}$ *and* $\sigma^{-1}\pi_{\vec{n}}$ *separates the points of* N*.*

Proof. Let us first deal with uniqueness. $\mathcal{V}_{\vec{n}}$ is determined by the equation $\mathcal{V}_{\vec{n}} = \sigma \vee \tau_{\vec{n}}$. If $\sigma^{-1}\pi$ separates the points of N then $\sigma^{-1}\pi_{\vec{n}}|_N = id_N$. Also $\pi_{\vec{n}}^{-1}\gamma_{p,q}$ is the identity on N^c, thus by Lemma 6 $\sigma^{-1}\gamma_{p,q}|_N = \sigma^{-1}\pi_{\vec{n}}|_N \cdot \pi_{\vec{n}}^{-1}\gamma_{p,q}|_N = \pi_{\vec{n}}^{-1}\gamma_{p,q}|_N$. And since $\pi_{\vec{n}}^{-1}\gamma_{p,q}\psi = \psi\pi^{-1}\gamma_{r,s}$ we see that π is uniquely determined.

Secondly let us prove existence. Let us denote by $NC(N_1)$ and $NC(N_2)$ respectively the non-crossing partitions of N_1 and N_2 where the order is that determined by $\gamma_{p,q}$. Similarly $S_{NC}(N_1, N_2)$ denotes the non-crossing annular permutations on $N_1 \cup N_2$, again with the order determined by $\gamma_{p,q}$.

By Lemma 5,

$$\sigma^{-1}\gamma_{p,q}|_N \in S_{NC}(N_1, N_2) \cup (NC(N_1) \times NC(N_2))$$

By assumption no cycle $\sigma^{-1}\gamma_{p,q}|_N$ meets both N_1 and N_2, so $\sigma^{-1}\gamma_{p,q}|_N \in NC(N_1) \times NC(N_2)$. Thus there is $\pi \in NC(r) \times NC(s)$ such that $\psi\pi^{-1}\gamma_{r,s}\psi^{-1} = \sigma^{-1}\gamma_{p,q}|_N$, and thus $\sigma^{-1}\gamma_{p,q}|_N = \pi_{\vec{n}}^{-1}\gamma_{p,q}|_N$. By Lemma 6, $\sigma^{-1}\pi_{\vec{n}}|_N = id_N$, so $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N.

Recall that $\pi_{\vec{n}}^{-1}\gamma_{p,q}(i) = i$ for $i \notin N$ and $\pi^{-1}\gamma_{p,q}|_N = \sigma^{-1}\gamma_{p,q}|_N$ thus $\pi_{\vec{n}}^{-1}\gamma_{p,q} \leq \sigma^{-1}\gamma_{p,q}$, and so by Corollary 21, $\sigma \vee \pi_{\vec{n}}$ is obtained from the cycles of $\pi_{\vec{n}}$ by joining the two cycles of $\pi_{\vec{n}}$, one from each circle, that meet the through cycles of σ. To complete the proof we must show that $\sigma \vee \tau_{\vec{n}} = \sigma \vee \pi_{\vec{n}}$, for this we must show that $\pi_{\vec{n}} \leq \sigma \vee \tau_{\vec{n}}$ i.e. that any two blocks of $\tau_{\vec{n}}$ connected by $\pi_{\vec{n}}$ are connected by σ.

Let c be a cycle of $\pi_{\vec{n}}$ not meeting a through cycle of σ and let $\tilde{\sigma}$ the product of the cycles of σ enclosed by c. Then $\tilde{\sigma}^{-1}c$ separates the points of N in c and so by Lemma 14 any two blocks of $\tau_{\vec{n}}$ in c connected by c are connected by $\tilde{\sigma}$.

Now let c and c' be the two cycles (one in each cycle of $\gamma_{p,q}$) that meet the through cycles of σ and let $\tilde{\sigma}$ be the product of the cycles of σ enclosed by $c \cup c'$ and the same for $\tilde{\tau}$. Now we must show that $\tilde{\sigma} \vee \tilde{\tau} = c \cup c'$. If not, then there would be $r \neq s \in N$ such that $(r, s) \leq \tilde{\sigma}^{-1}cc'$ in which case r and s are in the same cycle of $\sigma^{-1}\pi_{\vec{n}}$ contrary to our hypothesis. Hence $\sigma \vee \tau_{\vec{n}} = \pi_{\vec{n}}$. □

Proof of Theorem 3: Let us write $\phi_2(A_1 \cdots A_r, A_{r+1} \cdots A_{r+s})$ two different ways:

$$\begin{aligned}
\phi_2(A_1 \cdots A_r, A_{r+1} \cdots A_{r+s}) &= \sum_{\pi \in S_{NC}(r,s)} \kappa_\pi(A_1, \dots, A_{r+s}) \\
&\quad + \sum_{(\mathcal{V},\pi) \in \mathcal{PS}_{NC}(p,q)'} \kappa_{(\mathcal{V},\pi)}(A_1, \dots, A_{r+s}) \\
&= \sum_{\pi \in S_{NC}(r,s)} \kappa_\pi(A_1, \dots, A_{r+s}) \\
&\quad + \sum_{(\mathcal{V},\pi) \in \mathcal{PS}_{NC}(p,q)''} \kappa_{(\mathcal{V},\pi)}(A_1, \dots, A_{r+s}) \\
&\quad + \kappa_{r,s}(A_1, \dots, A_{r+s})
\end{aligned}$$

where $\mathcal{PS}_{NC}(r,s)'' = \mathcal{PS}_{NC}(r,s)' \setminus \{(1_{r+s}, \gamma_{r,s})\}$. Also

$$\begin{aligned}
\phi_2(A_1 \cdots A_r, A_{r+1} \cdots A_{r+s}) &= \phi_2(a_1 \cdots a_p, a_{p+1} \cdots a_{p+q}) \\
&= \sum_{\pi \in S_{NC}(p,q)} \kappa_\pi(a_1, \dots, a_{p+q}) \\
&\quad + \sum_{(\mathcal{V},\pi) \in \mathcal{PS}_{NC}(p,q)'} \kappa_{(\mathcal{V},\pi)}(a_1, \dots, a_{p+q})
\end{aligned}$$

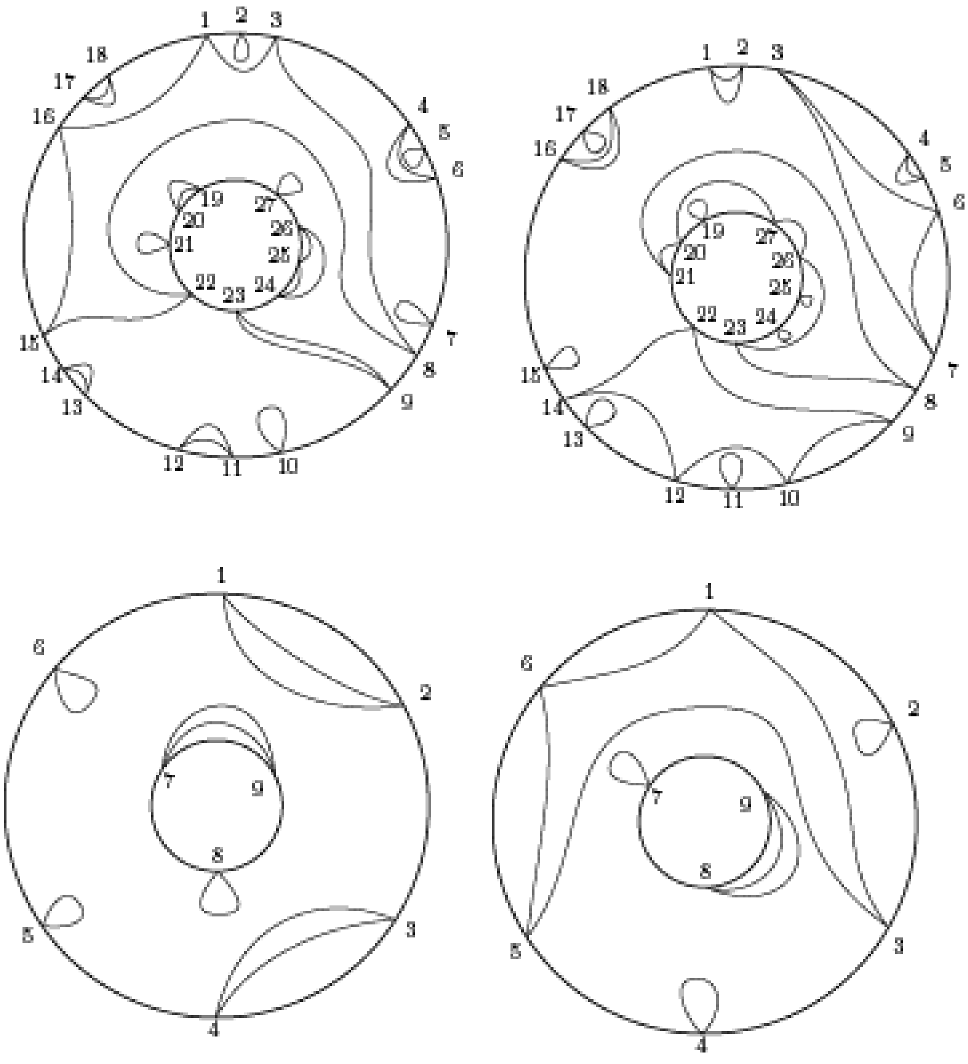

Figure 11. Shown is $\sigma \in S_{NC}(18,9)$ in the upper left, $\sigma^{-1}\gamma_{18,9}$ in the upper right. In the lower left we have $\pi^{-1}\gamma_{6,3}$ and the lower right we have $\pi \in S_{NC}(6,3)$. $\pi_{\vec{n}}$ is shown overleaf. Note that when $N = \{3,6,9,12,15,18,21,24,27\}$, σ satisfies the hypotheses of Lemma 29, for example 3 and 6 are in the same cycle of $\sigma^{-1}\gamma_{18,9}|_N$. The resulting $\pi^{-1}\gamma_{6,3}$ has 1 and 2 in the same cycle.

Now solving for $\kappa_{r,s}(A_1, \dots, A_{r+s})$ we have

$$\begin{aligned}\kappa_{r,s}(A_1, \dots, A_{r+s}) &= \sum_{\sigma \in S_{NC}(p,q)} \kappa_\sigma(a_1, \dots, a_{p+q}) \\ &\quad - \sum_{\pi \in S_{NC}(r,s)} \kappa_\pi(A_1, \dots, A_{r+s}) \\ &\quad + \sum_{(\mathcal{V},\pi) \in \mathcal{PS}_{NC}(p,q)} \kappa_{(\mathcal{V},\pi)}(a_1, \dots, a_{p+q}) \\ &\quad - \sum_{(\mathcal{V},\pi) \in \mathcal{PS}_{NC}(r,s)''} \kappa_{(\mathcal{V},\pi)}(A_1, \dots, A_{r+s})\end{aligned}$$

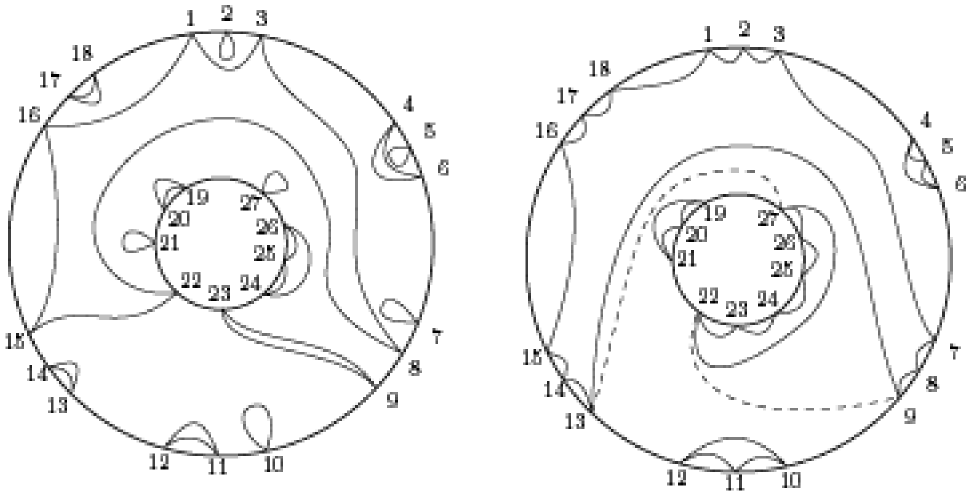

Figure 12. σ (left) from Figure 11 is compared with the $\pi_{\vec{n}} \in NC(18) \times NC(9)$ produced by Lemma 29. The two cycles of $\pi_{\vec{n}}$ that meet through cycles of σ are shown connected by dotted lines.

Now by Proposition 25

$$\sum_{\pi \in S_{NC}(r,s)} \kappa_\pi(A_1, \dots, A_{r+s}) = \sum_{\pi \in S_{NC}(r,s)} \sum_{\substack{\sigma \in S_{NC}(p,q) \\ \sigma^{-1}\pi_{\vec{n}} \text{ sep.'s } N}} \kappa_\sigma(a_1, \dots, a_{p+q})$$

If $\pi \in S_{NC}(r,s)$ and $\sigma^{-1}\pi_{\vec{n}}$ separates the points of N then $\sigma^{-1}\gamma_{p,q}|_N = \pi_{\vec{n}}^{-1}\gamma_{p,q}|_N$ by Lemma 6 and $\pi_{\vec{n}}^{-1}\gamma_{p,q}$ has a cycle that meets both N_1 and N_2. Conversely by Lemma 28 if $\sigma \in S_{NC}(p,q)$ is such that $\sigma^{-1}\gamma_{p,q}|_N$ has a cycle that meets both N_1 and N_2 then σ comes from a unique $\pi \in S_{NC}(r,s)$. Thus

$$\begin{aligned} \sum_{\sigma \in S_{NC}(p,q)} \kappa_\sigma(a_1, \dots, a_{p+q}) \quad - & \sum_{\pi \in S_{NC}(r,s)} \sum_{\substack{\sigma \in S_{NC}(p,q) \\ \sigma^{-1}\pi_{\vec{n}} \text{ sep.'s } N}} \kappa_\sigma(a_1, \dots, a_{p+q}) \\ &= \sum_{\substack{\sigma \in S_{NC}(p,q) \\ \sigma^{-1}\gamma_{p,q} \text{ sep.'s } N}} \kappa_\sigma(a_1, \dots, a_{p+q}) \end{aligned}$$

To conclude the proof we use induction on r and s. In Lemma 26 we have proved equation (9) when $r = s = 1$. We can apply the induction hypothesis to $\mathcal{PS}_{NC}(r,s)''$ because $(1_{r+s}, \gamma_{r,s})$ has been removed. Thus by Lemma 27 we have:

$$\begin{aligned}&\sum_{(\mathcal{V},\pi)\in\mathcal{PS}_{NC}(r,s)''}\kappa_{(\mathcal{V},\pi)}(A_1,\dots,A_{r+s})\\&=\sum_{(\mathcal{V},\pi)\in\mathcal{PS}_{NC}(r,s)''}\ \sum_{\substack{(\mathcal{U},\sigma)\in\mathcal{PS}_{NC}(p,q)'\\ \sigma^{-1}\pi_{\vec{n}}\text{ sep.'s }N}}\kappa_{(\mathcal{U},\sigma)}(a_1,\dots,a_{p+q})\\&=\sum_{\substack{(\mathcal{U},\sigma)\in\mathcal{PS}_{NC}(p,q)'\\ \sigma^{-1}\gamma_{p,q}\text{ does not sep. }N}}\kappa_{(\mathcal{U},\sigma)}(a_1,\dots,a_{p+q})\end{aligned}$$

where in the last sum not separating N means that no cycle of $\sigma^{-1}\gamma_{p,q}$ meets both N_1 and N_2 but some cycle of $\sigma^{-1}\gamma_{p,q}$ contains more than one point of N.

Hence

$$\sum_{(\mathcal{V},\pi)\in\mathcal{PS}_{NC}(p,q)'}\kappa_{(\mathcal{V},\pi)}(a_1,\dots,a_{p+q})-\sum_{(\mathcal{V},\pi)\in\mathcal{PS}_{NC}(r,s)''}\kappa_{(\mathcal{V},\pi)}(A_1,\dots,A_{r+s})$$

$$=\sum_{\substack{(\mathcal{U},\sigma)\in\mathcal{PS}_{NC}(p,q)'\\ \sigma^{-1}\gamma_{p,q}\text{sep.'s }N}}\kappa_{(\mathcal{U},\sigma)}(a_1,\dots,a_{p+q})$$

This proves Equation (9). □

4. First example – the square of a semi-circular operator

Let $(\mathcal{A},\phi)$ be a unital *-algebra with $\phi:\mathcal{A}\to\mathbb{C}$ a state. A self-adjoint element $x\in\mathcal{A}$ is called *semi-circular* if $\phi(x^{2k-1})=0$ and $\phi(x^{2k})=\frac{1}{k+1}\binom{2k}{k}$ for $k=1,2,3,\dots$ The element x is called semi-circular because the density of its spectral measure with respect to ϕ is $\frac{1}{2\pi}\sqrt{4-x^2}$. This density was shown by E. Wigner to be the limiting eigenvalue distribution of various ensembles of random matrices, in particular on ensemble usually known as the Gaussian Unitary ensemble (GUE). This ensemble can be described as follows.

For each positive integer N let $X_N=(f_{i,j})$ be the complex $N\times N$ self-adjoint random matrix such that

- $f_{i,j}=x_{ij}+\sqrt{-1}y_{ij}$;
- for $i\neq j$, x_{ij} and y_{ij} are real Gaussian random variables with mean 0 and variance $1/(2N)$;
- for each i, x_{ii} is a real Gaussian random variable with mean 0 and variance $1/N$
- $\{x_{ij}\}_{i\le j}\cup\{y_{ij}\}_{i<j}$ is an independent set of random variables

Other descriptions exist, see for example Deift [8, §5.2] or Hiai and Petz [12, §4.1].

The theorem of Wigner asserts that the limiting eigenvalue distribution of X_N has the semi-circular density given above. In particular the limiting moments (α_k) are those of a semi-circular operator: $\alpha_{2k-1} = 0$ and $\alpha_{2k} = \frac{1}{k+1}\binom{2k}{k}$ for $k \geq 1$.

In [13] Johansson considered the asymptotic behaviour of the random variables $\{\mathrm{Tr}(X_N^k - \alpha_k I_N)\}_k$ for a class of ensembles containing the GUE. He showed that the random variables were asymptotically Gaussian and showed that the Chebyshev polynomials of the first kind diagonalized the covariance.

In [21] Mingo and Nica showed that the limiting covariances $\alpha_{p,q} = \lim_N \mathrm{E}(\mathrm{Tr}(X_N^p - \alpha_p I_N)\,\mathrm{Tr}(X_N^q - \alpha_q I_N))$, sometimes called the *fluctuation moments*, were positive integers which count the number of non-crossing pairings of a (p, q)-annulus. These are the elements of $S_{NC}(p, q)$ for which all cycles are of length 2. These diagrams or equivalent formulations had already been used in a variety of earlier papers: Tutte [27] and [28], Jones [14], and King [16] where it was found that

$$\alpha_{p,q} = \sum_{k\geq 1} k \binom{p}{\frac{p-k}{2}} \binom{q}{\frac{q-k}{2}} \tag{11}$$

$$= \begin{cases} \dfrac{pq}{2p+2q} \dbinom{p}{\frac{p}{2}} \dbinom{q}{\frac{q}{2}} & p \text{ and } q \text{ are even} \\[2ex] \dfrac{(p+1)(q+1)}{8p+8q} \dbinom{p+1}{\frac{p+1}{2}} \dbinom{q+1}{\frac{q+1}{2}} & p \text{ and } q \text{ are odd} \end{cases}$$

The first expression for $\alpha_{p,q}$ can be seen by observing that every non-crossing pairing of a (p, q)-annulus with k through strings (i.e. strings that connect the two circles) can be obtained by connecting a non-crossing pairing of $[p]$ with one block of size k and the others of size 2, with a non-crossing partition of $[q]$ with one block of size k and the others of size 2; and then invoking Kreweras [18, Théorème 2] and finally summing over k.

It is natural then to define $(\alpha_{p,q})_{p,q}$ to be the fluctuation moments of the semi-circular operator.

Let $\mathcal{A} = \mathbb{C}[x]$ be the polynomials in x. Define $\phi : \mathcal{A} \to \mathbb{C}$ by $\phi(x^k) = \alpha_k$ where $(\alpha_k)_k$ are the moments of the semi-circular operator. Define $\phi_2(x^p, x^q) = 0$ if $p = 0$, $q = 0$, or $p+q$ is odd and $\phi_2(x^p, x^q) = \alpha_{p,q}$ (as defined in Equation (11)) if $p + q$ is even. One then extends ϕ and ϕ_2 by linearity. Notice that the choice of ϕ_2 is independent of ϕ.

Now $(\mathcal{A}, \phi, \phi_2)$ is a second order non-commutative probability space and we can consider the cumulants of x. It is a standard calculation to see that $\kappa_n(x, x, \dots, x)$ is 0 for all $n \neq 2$ and $\kappa_2(x, x) = 1$. In the case of second order cumulants, $(\kappa_{p,q})_{p,q}$ are all 0. We can see this directly from Equation (8) which states:

$$\begin{aligned} \phi_2(x^p, x^q) = &\sum_{\pi \in S_{NC}(p,q)} \kappa_\pi(x, \dots, x) \\ &+ \sum_{(\mathcal{V},\pi) \in \mathcal{PS}_{NC}(p,q)'} \kappa_{(\mathcal{V},\pi)}(x, \dots, x) \end{aligned} \tag{12}$$

Because x is semi-circular, $\kappa_\pi(x, \dots, x)$ is 0 unless π is a pairing in which case $\kappa_\pi(x, \dots, x)$ is 1. Thus the first term on the right hand side of (12) is $\alpha_{p,q}$. Since by definition the left hand side is also $\alpha_{p,q}$ we have that $\sum_{(\mathcal{V},\pi) \in \mathcal{PS}_{NC}(p,q)'} \kappa_{(\mathcal{V},\pi)}(x, \dots, x) = 0$ for all p and q. Hence for $p = q = 1$, $\kappa_{1,1}(x, \dots, x) = 0$ as there is only one term. Now $\kappa_{p,q}(x, \dots, x)$ only appears once in the expression $\sum_{(\mathcal{V},\pi) \in \mathcal{PS}_{NC}(p,q)'} \kappa_{(\mathcal{V},\pi)}(x, \dots, x)$, all the other terms have a factor of $\kappa_{r,s}(x, \dots, x)$ for either $r < p$ and $s \leq q$ or $r \leq p$ and $s < q$. Thus by induction $\kappa_{p,q}(x, \dots, x) = 0$ for all p and q.

Now let $a = x^2$. We shall use Theorem 3 to show that the second order cumulants $\kappa_{p,q} = \kappa_{p,q}(a, \dots, a)$ have the generating function

$$C(z, w) = \sum_{p,q \geq 1} \kappa_{p,q} z^p w^q = \frac{zw}{(1 - z - w)^2}$$

and thus

$$\kappa_{p,q} = p \binom{p + q - 1}{p}$$

First let us recall the first order cumulants of a. Let $N = \{2, 4, 6, \dots, 2n\}$. By Equation (4) and Theorem 15

$$\kappa_n(a, \dots, a) = \kappa_n(x^2, \dots, x^2) = \sum_{\substack{\pi \in NC(2n) \\ \pi^{-1}\gamma_{2n} \text{ sep.'s } N}} \kappa_\pi(x, \dots, x)$$

Now as noted above $\kappa_\pi(x, \dots, x) = 0$ unless π is a pairing. Let π be a pairing such that $\pi^{-1}\gamma_{2n}$ separates the points of N. Since π is non-crossing 2 is connected to $2k + 1$ for some k. Then 2 and $2k$ are in the same cycle of $\pi^{-1}\gamma_{2n}$ unless $k = 1$, i.e. 2 is connected to 3. In general we must have that $2k$ is connected to $2k + 1$ for $1 \leq k < n$ and $2n$ is connected to 1. Thus there is only one pairing such that $\pi^{-1}\gamma_{2n}$ separates the points of N. The contribution of this pairing is 1. Hence $\kappa_n(a, \dots, a) = 1$ for all n.

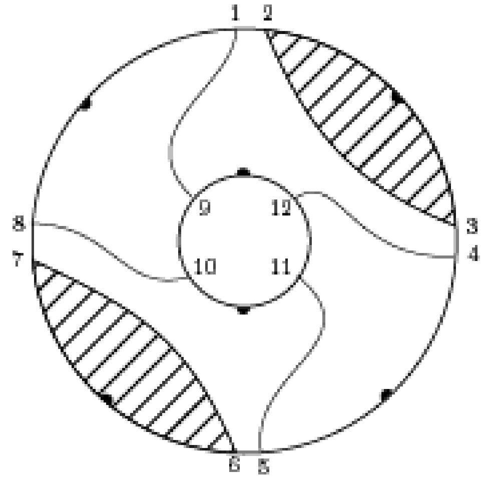

Figure 13. An example of a pairing π of the $(8,4)$-annulus such that $\pi^{-1}\gamma_{8,4}$ separates the points of $\{2,4,6,8,10\}$. To construct such a pairing we choose $p-k$ dots on one circle and $q-k$ dots on the other circle and cover these with a pairing (dots 2 and 6 covered with the shading above). All remaining points are connected with through strings. In this example there are only two ways to make the connections: 1 is connected to either 9 or 11; this choice forces all the others.

Now let us find the second order cumulants of a. Fix p and q and let $N = \{2, 4, 6, \ldots, 2p+2q\}$.

$$\begin{aligned}
\kappa_{p,q}(a,\ldots,a) &= \kappa_{p,q}(x^2,\ldots,x^2) \\
&= \sum_{\substack{\pi\in S_{NC}(2p,2q) \\ \pi^{-1}\gamma_{2p,2q} \text{ sep.'s } N}} \kappa_\pi(x,\ldots,x) + \sum_{\substack{(\mathcal{V},\pi)\in\mathcal{PS}_{NC}(2p,2q)' \\ \pi^{-1}\gamma_{2p,2q} \text{ sep.'s } N}} \kappa_{(\mathcal{V},\pi)}(x,\ldots,x) \\
&= \sum_{\substack{\pi\in S_{NC}(2p,2q) \\ \pi^{-1}\gamma_{2p,2q} \text{ sep.'s } N}} \kappa_\pi(x,\ldots,x)
\end{aligned}$$

because, as we have shown, all the second order cumulants of x are 0. Moreover as noted above $\kappa_\pi(x,\ldots,x) = 0$ except for π a pairing in which case we get 1. Thus $\kappa_{p,q}(a,\ldots,a)$ is the cardinality of $\{\pi \in S_{NC}(2p,2q) \mid \pi \text{ is a pairing and } \pi^{-1}\gamma_{2p,2q} \text{ separates the points of } N\}$.

Proposition 30. $\kappa_{p,q}(a,\ldots,a) = \sum_{k\geq 1} k\binom{p}{k}\binom{q}{k}$

Proof. We shall show that the number of non-crossing pairings π of a $(2p, 2q)$-annulus with k pairs of through strings such that $\pi^{-1}\gamma_{2p,2q}$ separates the points of $N = \{2, 4, 6, \ldots, 2p + 2q\}$ is $k\binom{p}{k}\binom{q}{k}$. Summing over k establishes our claim.

Let π be a non-crossing pairing π of a $(2p, 2q)$-annulus with k pairs of through strings such that $\pi^{-1}\gamma_{2p,2q}$ separates the points of N. By the same argument as in the disc case the only possible pairs of π which are not through strings are of the form $(2t, 2t + 1)$. There are $\binom{p}{k} = \binom{p}{p-k}$ ways to place these $p-k$ pairs of adjacent elements on $[2p]$ and $\binom{q}{k} = \binom{q}{q-k}$ ways of placing these $q - k$ pairs of adjacent elements on $[2p + 1, 2p + 2q]$. In principle there are $2k$ ways of connecting the $2k$ through strings but half of these put two elements of N in the same cycle of $\pi^{-1}\gamma_{2p,2q}$, so in practice there are only k ways of connecting the through strings. Thus the number of pairings is indeed $k\binom{p}{k}\binom{q}{k}$. See Figure XX.

□

Theorem 31.

$$\sum_{p,q\geq 1} \kappa_{p,q}(a, \ldots, a) z^p w^q = \frac{zw}{(1 - z - w)^2} = \sum_{p,q\geq 1} p\binom{p + q - 1}{p} z^p w^q$$

Proof.

$$\begin{aligned}
\sum_{p,q\geq 1} \kappa_{p,q}(a, \ldots, a) z^p w^q &= \sum_{p,q\geq 1} \sum_{k\geq 1} k\binom{p}{k}\binom{q}{k} z^p w^q \\
&= \sum_{k\geq 1} k \sum_{p\geq 1}\binom{p}{k} z^p \sum_{q\geq 1}\binom{q}{k} w^q = \sum_{k\geq 1} k \frac{z^k}{(1-z)^{k+1}} \frac{w^k}{(1-w)^{k+1}} \\
&= \frac{zw}{[(1-z)(1-w)]^2} \sum_{k\geq 1} k \left(\frac{zw}{(1-z)(1-w)}\right)^{k-1} \\
&= \frac{zw}{[(1-z)(1-w)]^2} \frac{1}{(1 - \frac{zw}{(1-z)(1-w)})^2} = \frac{zw}{(1 - z - w)^2}
\end{aligned}$$

Continuing we have

$$\begin{aligned}
\frac{zw}{(1-z-w)^2} &= \sum_{k\geq 1} k(z+w)^{k-1}zw = \sum_{k\geq 1}\sum_{p=0}^{k-1} k\binom{k-1}{p} z^{p+1}w^{k-p} \\
&= \sum_{k,p\geq 1} k\binom{k-1}{p-1} z^p w^{k+1-p} \\
&= \sum_{p,q\geq 1} (p+q-1)\binom{p+q-2}{p-1} z^p w^q \quad \left\{ \begin{array}{l} \textit{letting } q = \\ k+1-p \end{array} \right. \\
&= \sum_{p,q\geq 1} p\binom{p+q-1}{p} z^p w^q
\end{aligned}$$

□

Let us next outline a method for establishing the same result that uses the second order R-transform in Equation (1) or the equivalent formulation given in [7, Equation (52)]. Let $C(z,w) = 1 + zwR(z,w)$, and $M(z) = \sum_{k\geq 0} \phi(a^k)z^k$ be the moment generating function of a, and $M(z,w) = \sum_{p,q\geq 1} \phi_2(a^p, a^q)z^p w^q$ be the fluctuation moment generating function of a. Then Equation (1) becomes

$$\begin{aligned}
C(zM(z), wM(w)) &= \left(M(z,w) + \frac{zw}{(z-w)^2} \right) \frac{M(z)}{\frac{d}{dz}(zM(z))} \frac{M(w)}{\frac{d}{dw}(wM(w))} \\
&\quad - \frac{zM(z)wM(w)}{(zM(z)-wM(w))^2} \qquad (13)
\end{aligned}$$

We must find the fluctuation moment generating function $F(z,w)$ of the semi-circular operator. Let

$$F(z) = \sum_{k\geq 0} \phi(x^k) = \frac{1-\sqrt{1-4z^2}}{2z^2} \qquad \text{and}$$

$$\begin{aligned}
F(z,w) = \sum_{p,q\geq 1} \phi_2(x^p, x^q)z^p w^q &= \frac{z\frac{d}{dz}(zF(z))w\frac{d}{dz}(wF(w))}{(1-zF(z)wF(w))^2} \\
&= \frac{zw(zF(z)-wF(w))^2}{(z-w)^2(1-z^2F(z)^2)(1-w^2F(w)^2)}
\end{aligned}$$

Where we obtain the second last expression for $F(z,w)$ by using the first expression for $\alpha_{p,q}$ in Equation (11), then Lambert's identity [11, equation 5.21], and finally summing over k, and the last expression is obtained from the quadratic equation satisfied by F.

Now

$$M(z^2) = F(z) \text{ and } M(z^2, w^2) = \frac{1}{2}(F(z,w) + F(-z,w))$$

Thus

$$M(z,w) = \frac{2zwM(z)^3M(w)^3}{(2 - M(z))(2 - M(w))(1 - zM(z)^2wM(w)^2)^2}$$

If we make the substitution $u = zM(z)$ and $v = wM(w)$ then we have

$$M(z) = \frac{1}{1-u}, \ z = u - u^2, \ \frac{d}{dz}(zM(z)) = \frac{1}{1-2u}, \text{ and}$$

$$M(z,w) = \frac{2uv(1-u)(1-v)}{(1-2u)(1-2v)(1-u-v)^2}$$

Thus

$$M(z,w) + \frac{zw}{(z-w)^2} = \frac{uv(1-u)(1-v)(1-2u-2v+2u^2+2v^2)}{(1-2u)(1-2v)(u-v)^2(1-u-v)^2}$$

After some routine manipulations it follows from (13) and the equation above that

$$C(u,v) = \frac{uv}{(1-u-v)^2}$$

5. Second Example – a Haar Unitary

Let $(\mathcal{A}, \phi)$ be a non-commutative probability space and $u \in \mathcal{A}$ a unitary. Recall (see e.g. [24, Lecture 10]) that u is a Haar unitary if $\phi(u^k) = 0$ for $k \neq 0$. In [24] it is shown that for $\epsilon_1, \epsilon_2, \ldots, \epsilon_n \in \{-1, 1\}$ then $\kappa_n(u^{\epsilon_1}, u^{\epsilon_2}, \ldots, u^{\epsilon_n}) = 0$ unless n is even and $\epsilon_1 + \epsilon_2 = \epsilon_2 + \epsilon_3 = \cdots = \epsilon_{n-1} + \epsilon_n = 0$; i.e. all the free cumulants of $\{u, u^*\}$ are 0 except for the alternating ones: $\kappa_n(u, u^*, \ldots, u, u^*) = \kappa_n(u^*, u, \ldots, u^*, u)$ which equal $\mu(0_n, 1_n) = (-1)^{n-1}c_{n-1}$ where μ is the Möbius function of the lattice $NC(n)$ and c_n is the n^{th} Catalan number. We wish here to indicate the corresponding result for the second order cumulants of u and u^*. The proofs will be given in a another paper.

We first have to decide how to define the fluctuation moments of a Haar unitary. In [10, Theorem 2], Diaconis and Shahshahani showed that if U_N is an $N \times N$ Haar distributed random unitary then

$$\mathrm{E}(\mathrm{Tr}(U_N^k)\,\mathrm{Tr}(U_N^{-k})) = |k| \text{ for } N \geq 2$$

We shall use these fluctuation moments to define our second order Haar unitary.

Definition 32. Let $(\mathcal{A}, \phi, \phi_2)$ be a second order probability space and $u \in \mathcal{A}$ a unitary. We say that u is a second order Haar unitary if $\phi(u^k) = 0$ for $k \neq 0$ (i.e. u is a Haar unitary) and for all integers k, $\phi_2(u^k, u^l) = \delta_{k,-l}|k|$.

Proposition 33. *Let p and q be positive integers and u a second order Haar unitary. Let $\epsilon_1, \epsilon_2, \epsilon_3, \dots, \epsilon_{p+q} \in \{-1, 1\}$. Then $\kappa_{p,q}(u^{\epsilon_1}, u^{\epsilon_2}, \dots, u^{\epsilon_{n-1}}, u^{\epsilon_n}) = 0$ unless p and q are even and*

$$\epsilon_1 + \epsilon_2 = \cdots = \epsilon_{p-1} + \epsilon_p = \epsilon_{p+1} + \epsilon_{p+2} = \cdots = \epsilon_{p+q-1} + \epsilon_{p+q} = 0 \tag{14}$$

i.e. the ϵ's alternate in sign except possibly between p and $p + 1$.

As noted above, in the first order case the alternating cumulants of u and u^* were given by the Möbius function μ of the lattice $NC(n)$, i.e.

$$\kappa_{2n}(u, u^*, \dots, u, u^*) = \kappa_{2n}(u^*, u, \dots, u^*, u) = \mu(0_n, 1_n)$$

We shall state an analogous result for the second order case. Recall from [7, §5.4] that the second order Möbius function is defined as the multiplicative function which is the convolution inverse of the zeta function on the set of partitioned permutations. It was shown [7, Theorem 5.24] that $\mu(1_n, \gamma_n) = (-1)^{n-1}c_{n-1}$ and $\mu(1_{p+q}, \gamma_{p,q}) = (-1)^{p+q}c_{p,q}$ where $c_{p,q}$ is the cardinality of $S_{NC}(p, q)$. Moreover it was shown [7, page 46] that the the Möbius function satisfies the following recurrence relation

$$\begin{aligned} 0 &= \mu(1_{p+q}, \gamma_{p,q}) + q\mu(1_{p+q}, \gamma_{p+q}) \\ &\quad + \sum_{1 \le k < p} \Big(\mu(1_{k+q}, \gamma_{k,q})\mu(1_{p-k}, \gamma_{p-k}) + \mu(1_k, \gamma_k)\mu(1_{p-k+q}, \gamma_{p-k,q}) \Big) \end{aligned}$$

The alternating cumulants of u and u^* satisfy the same recurrence relation.

Theorem 34. *Let $p = 2m$ and $q = 2n$ be even integers and $\epsilon_1, \dots, \epsilon_{p+q} \in \{-1, 1\}$ satisfy (14). Then $\kappa_{p,q}(u^{\epsilon_1}, \dots, u^{\epsilon_{p+q}}) = (-1)^{m+n}c_{m,n}$.*

6. CONCLUDING REMARKS – A PARTIAL ORDER ON $\mathcal{PS}_{NC}(p, q)$

In §2 we proved two lemmas (19 and 20) that show that if π is a sub-partition of the Kreweras complement $\sigma^{-1}\gamma_{p,q}$ of σ, then σ is a sub-partition of the Kreweras complement $\gamma_{p,q}\pi^{-1}$ of π, provided we take the complement on the other side. In Lemma 20 this order was expressed terms of multiplication of partitioned permutations. The multiplication of partitioned permutations can be used to make $\mathcal{PS}_{NC}(p, q)$ into a partially ordered set. This order is an extension of the one given in Definition 17.

Definition 35. If $(\mathcal{V}, \pi), (\mathcal{U}, \sigma) \in \mathcal{PS}_{NC}(p, q)$ we say that $(\mathcal{V}, \pi) \leq (\mathcal{U}, \sigma)$ if there is $\mathcal{W}$ such that $(\mathcal{V}, \pi) \cdot (\mathcal{W}, \pi^{-1}\sigma) = (\mathcal{U}, \sigma)$.

Proposition 36. *Let* $(\mathcal{V}, \pi), (\mathcal{U}, \sigma) \in \mathcal{PS}_{NC}(p, q)$ *and suppose there is* $\mathcal{W}$ *such that* $(\mathcal{V}, \pi) \cdot (\mathcal{W}, \pi^{-1}\sigma) = (\mathcal{U}, \sigma)$*. Then*

i) $\mathcal{W} = 0_{\pi^{-1}\sigma}$ *and*
ii) $\mathcal{U} = \mathcal{V} \vee \pi^{-1}\sigma = \mathcal{V} \vee \pi \vee \sigma = \mathcal{V} \vee \sigma\pi^{-1}$*;*
iii) $(0_{\sigma\pi^{-1}}, \sigma\pi^{-1}) \cdot (\mathcal{V}, \pi) = (\mathcal{U}, \sigma)$*.*

Proof. Recall that for $(\mathcal{V}, \pi) \in \mathcal{PS}_{NC}(p, q)$ either $\pi \in S_{NC}(p, q)$ and $\mathcal{V} = 0_\pi$ or $\pi \in NC(p) \times NC(q)$ and all the blocks of $\mathcal{V}$ contain just one cycle of π except one block of $\mathcal{V}$ which contains two cycles of π – one from each circle; thus in this case $|\mathcal{V}| = |\pi| + 1$. Hence in the former case $|(\mathcal{V}, \pi)| = |\pi|$ and in the latter case $|(\mathcal{V}, \pi) = |\pi| + 2$.

Thus $|(\mathcal{V}, \pi)| = |\pi| + \delta$ where $\delta = 0$ or 2. By assumption $|(\mathcal{V}, \pi)| + |(\mathcal{W}, \pi^{-1}\sigma)| = |(\mathcal{U}, \sigma)|$. If $\sigma \in S_{NC}(p, q)$ then $\mathcal{U} = 0_\sigma$ and $|(\mathcal{U}, \sigma)| = |\sigma|$. Thus

$$|\pi| + \delta + |(\mathcal{W}, \pi^{-1}\sigma)| = |\sigma| \leq |\pi| + |\pi^{-1}\sigma|$$

Therefore $\delta = 0$ and $|(\mathcal{W}, \pi^{-1}\sigma)| = |\pi^{-1}\sigma|$ and so $\mathcal{W} = 0_{\pi^{-1}\sigma}$.

Suppose that $\sigma \in NC(p) \times NC(q)$ then $|\mathcal{U}| = |\sigma| + 1$ and $|(\mathcal{U}, \sigma)| = |\sigma| + 2$. If $\pi \in NC(p) \times NC(q)$ then $|(\mathcal{V}, \pi)| = |\pi| + 2$ and again we can use the triangle inequality

$$|\pi| + 2 + |(\mathcal{W}, \pi^{-1}\sigma)| = |\sigma| + 2 \leq |\pi| + 2 + |\pi^{-1}\sigma|$$

to conclude that $\mathcal{W} = 0_{\pi^{-1}\sigma}$. When $\pi \in S_{NC}(p, q)$ we have to appeal to [7, Proposition 5.11] and for this we need a little preparation.

Let the cycles of σ be $c_1, c_2, \ldots, c_{k+1}$ and the blocks of $\mathcal{U}$ be $\{U_1, \ldots, U_k\}$ with $U_i = c_i$ as sets for $1 \leq i < k$ and $U_k = c_k \cup c_{k+1}$ also as sets. Then we can write $\pi = \pi_1 \pi_2 \cdots \pi_k$ when π is the product of the cycles of π contained in U_i. We can also decompose $\mathcal{V}$ and $\mathcal{W}$ into $\mathcal{V}_1, \mathcal{V}_2, \ldots, \mathcal{V}_k$ and $\mathcal{W}$ into $\mathcal{W}_1, \mathcal{W}_2, \ldots, \mathcal{W}_k$ along the blocks of $\mathcal{U}$. By the triangle inequality we have that

$$\begin{cases} |(U_i, c_i)| \leq |(\mathcal{V}_i, \pi_i)| + |(\mathcal{W}_i, \pi_i^{-1} c_i)| & \text{for } 1 \leq i < k \text{ and} \\ |(U_k, c_k c_{k+1})| \leq |(\mathcal{V}_k, \pi_k)| + |(\mathcal{W}_k, \pi_k^{-1} c_k c_{k+1})| \end{cases} \tag{15}$$

Directly from the definition of $|\cdot|$ we obtain that

$$|(\mathcal{V}, \pi)| = |(\mathcal{V}_1, \pi_1)| + \cdots + |(\mathcal{V}_k, \pi_k)|$$

$$|(\mathcal{W}, \sigma)| = |(\mathcal{W}_1, \pi_1^{-1} c_1)| + \cdots + |(\mathcal{W}_k, \pi_k^{-1} c_k c_{k+1})|$$

and

$$|(\mathcal{U}, \sigma)| = |(\mathcal{U}_1, c_1)| + \cdots + |(\mathcal{U}_k, c_k c_{k+1})|$$

Hence

$$\begin{aligned}|(\mathcal{V}_1,\pi_1)| \quad + \quad & \cdots + |(\mathcal{V}_k,\pi_k)| + |(\mathcal{W}_1,\pi_1^{-1}c_1)| + \cdots \\ & + |(\mathcal{W}_k,\pi_k^{-1}c_kc_{k+1})| = |(\mathcal{U}_1,c_1)| + \cdots + |(\mathcal{U}_k,c_kc_{k+1})|\end{aligned}$$

If there were a strict inequality in any of the inequalities (15) then we would have strict inequality in the equality above. Since we don't, all the inequalities in (15) must be equalities. Hence

$$|(U_i,c_i)| = |(\mathcal{V}_i,\pi_i)| + |(\mathcal{W}_i,\pi_i^{-1}c_i)| \text{ for } 1 \leq i < k \text{ and}$$
$$|(U_k,c_kc_{k+1})| = |(\mathcal{V}_k,\pi_k)| + |(\mathcal{W}_k,\pi_k^{-1}c_kc_{k+1})|$$

Thus for each $i < k$, $\mathcal{W}_i = 0_{\pi_i^{-1}c_i}$ and π_i is a non-crossing partition of c_i. The last equality shows that $(\mathcal{V}_k,\pi_k)\cdot(\mathcal{W}_k,\pi_k^{-1}c_kc_{k+1}) = (\mathcal{U}_k,c_kc_{k+1})$. By [7, Proposition 5.11] we have that $\mathcal{W}_k = 0_{\pi_k^{-1}c_kc_{k+1}}$ and thus $\mathcal{W} = 0_{\pi^{-1}\sigma}$. Moreover $(\mathcal{V}_k,\pi_k)$ is in $\mathcal{PS}_{NC}(c_k,c_{k+1})$. This proves (i).

Since π and σ are permutations the orbits of the subgroups generated by $\{\pi,\sigma\}$, $\{\pi,\pi^{-1}\sigma\}$, and $\{\pi,\sigma\pi^{-1}\}$ are all the same. Thus as partitions $\pi\vee\sigma = \pi\vee\pi^{-1}\sigma = \pi\vee\sigma\pi^{-1}$. Since $\pi\leq\mathcal{V}$ we have $\mathcal{U} = \mathcal{V}\vee\pi^{-1}\sigma = \mathcal{V}\vee\pi\vee\sigma = \mathcal{V}\vee\pi\vee\sigma\pi^{-1} = \mathcal{V}\vee\sigma\pi^{-1}$. This proves (ii) and (iii) follows from (ii). ☐

Remark 37. Associativity of multiplication of partitioned permutations ([7, Proposition 4.10]) shows that the partial order is transitive. Indeed, suppose $(\mathcal{V},\pi),(\mathcal{U},\sigma),(\mathcal{W},\tau)\in\mathcal{PS}_{NC}(p,q)$ and that $(\mathcal{V},\pi)\leq(\mathcal{U},\sigma)$ and $(\mathcal{U},\sigma)\leq(\mathcal{W},\tau)$. Then

$$(\mathcal{V},\pi)\cdot(0_{\pi^{-1}\sigma},\pi^{-1}\sigma) = (\mathcal{U},\sigma) \text{ and } (\mathcal{U},\sigma)\cdot(0_{\sigma^{-1}\tau},\sigma^{-1}\tau) = (\mathcal{W},\tau)$$

Then

$$(\mathcal{V},\pi)\cdot(0_{\pi^{-1}\sigma}\vee 0_{\sigma^{-1}\tau},\pi^{-1}\tau) = (\mathcal{W},\tau)$$

and incidentally from Proposition 36 that as partitions $\pi^{-1}\sigma\vee\sigma^{-1}\tau = \pi^{-1}\tau$

Corollary 38. *Let $(\mathcal{V},\pi),(\mathcal{U},\sigma)\in\mathcal{PS}_{NC}(p,q)$. Then $(\mathcal{V},\pi)\leq(\mathcal{U},\sigma)$ if and only if*

- *i)* *$\mathcal{V}\leq\mathcal{U}$;*
- *ii)* *if $\sigma\in S_{NC}(p,q)$ then $\pi\in S_{NC}(p,q)$ and every cycle of π is contained in a cycle of σ and for each cycle of σ the enclosed cycles of π form a non-crossing permutation of this cycle of σ;*
- *iii)* *if $\sigma\in NC(p)\times NC(q)$ then every cycle of π is contained in either a cycle of σ or the union of the two cycles of σ connected by $\mathcal{U}$; and for every cycle of σ or the union of the two cycles joined by $\mathcal{U}$ the enclosed cycles of π form a non-crossing permutation of this cycle or union of two cycles.*

Remark 39. In [7, Notation 5.11] a partitioned permutation $(\mathcal{V}, \pi)$ with $\mathcal{V} = 0_\pi$ was called a *disc permutation* and one where $|\mathcal{V}| = |\pi| + 1$ a *tunnel permutation.* With our order on $\mathcal{PS}_{NC}(p, q)$ we see that we can have: (i) disc $\leq$ disc, (ii) disc $\leq$ tunnel; and (iii) tunnel $\leq$ tunnel; but tunnel $\not\leq$ disc.

Remark 40. With this order, $\mathcal{PS}_{NC}(p, q)$ becomes a partially ordered set and the Möbius function of the poset $\mathcal{PS}_{NC}(p, q)$ has a simple relation to the Möbius function introduced in [7, §5.4] and used in §5. We will address this relation in a forthcoming paper.
